Introduction 1

This book will eventually become the reference manual of LuATEX. At the moment, it simply reports the behaviour of the executable matching the snapshot date in the title page.

Features may come and go. The current version of LUATEX is not meant for production and users cannot depend on functionality staying the same.

Nothing in the API is considered stable just yet. This manual therefore simply reflects the current state of the executable. Absolutely nothing on the following pages is set in stone. When the need arises, anything can (and will) be changed without prior notice.

If you are unhappy with this situation, wait for the public betas.

LUATEX consists of a number of interrelated but (still) distinguishable parts:

- PDFTFX version 1.40.3
- ALEPH RC4 (from the TEXLIVE repository)
- Functionality of ε -T_FX 2.2
- Lua 5.1.2
- Dedicated Lua libraries
- Various T_FX extensions
- The (OPENTYPE) Font Parser from FontForge 2006.12.20
- Compiled source code to glue it all together

Neither I/O translation processes, nor tcx files, nor ENCTEX can be used. All these encoding-related functions are superseded by a Lua-based solution (reader callbacks).

Basic TEX enhancements

UNICODE support

Text input and output is now considered to be UNICODE text, so characters can use the full range of UNICODE $(2^{20} + 2^{16} = 10FFFF = 1114111)$.

For now, it only makes sense to use values above the base plane (FFFF) for \mathcode and \catcode assignments, since the hyphenation patterns are still limited to at the most 16-bit values, so the other commands will not know what to do with those high values.

Many primitives are affected by this. For instance, \char now accepts values between 0 and 1114111. This should not be a problem for well-behaved input files, but it could create incompatibilities for input that would have generated an error when processed by older TFX-based engines. The maximum number of allocations is "10FFFF or $2^{20} + 2^{16}$ (21 bits). The maximum value that can be assigned are:

primitive	bits	hex	numeric
\char	21	10FFFF	$2^{20} + 2^{16}$
\chardef	21	10FFFF	$2^{20} + 2^{16}$
\lccode	21		$2^{20} + 2^{16}$
\uccode	21	10FFFF	$2^{20} + 2^{16}$
\sfcode	15	7FFF	2 ¹⁵
\catcode	4	F	2^4
\mathchardef	15	8000	$2^3 \times 2^8 \times 2^4$
\mathcode	15	8000	$2^3 \times 2^8 \times 2^4$
\delcode	27	7FFFFFF	$2^3 \times 2^4 \times 2^8 \times 2^4 \times 2^8$

As far as the core engine is concerned, all input and output to text files is UTF-8 encoded. Input files can be pre-processed using the reader callback. This will be explained in a later chapter.

Output in byte-sized chunks can be achieved by using characters in the private use block that starts at index 1.113.856 (10FF00). When the times comes to print a character c >= 1.113.856, LuATFX will actually print the single byte corresponding to c - 1.113.856.

Output to the terminal uses $\hat{\ }$ notation for the lower control range (c < 32), with the exception of $\hat{\ }$ I, ^^J and ^^M. These are considered safe and therefore printed as-is.

Normalization of the UNICODE input can be handled by a macro package during callback processing (will be explained below).

Wide math characters

Text is now extended up to the full UNICODE range, but math mode deals mostly with glyphs in fonts directly, and fonts tend to be 16-bit at maximum.

Therefore, the math primitives from Aleph are kept mostly as-is, except for the ones that convert from input to math commands. The extended commands (with the o prefix) accept 16-bit glyph indices in one of 256 possible families. The traditional TEX primitives are unchanged, their arguments are upscaled internally.

primitive	max index/bits	hex		numeric
\mathchar	15	7FFF		$2^3 * 2^8 * 2^4$
\delimiter	27	7FFFFFF		$2^3 * 2^4 * 2^8 * 2^4 * 2^8$
\omathchar	27	7FFFFFF		$2^3 * 2^{16} * 2^8$
\odelimiter	27+24	7FFFFFF +	FFFFFF	$2^3 * 2^8 * 2^{16} + 2^8 * 2^{16}$
\omathchardef	21=27	10FFFF =	8000000	$2^{20} + 2^{16} = 2^3 * 2^{16} * 2^8$
\omathcode	21=27	10FFFF =	8000000	$2^{20} + 2^{16} = 2^3 * 2^{16} * 2^8$
\odelcode	21 = 27 + 24	10FFFF =	7FFFFFF	$2^{20} + 2^{16} = 2^3 * 2^8 * 2^{16}$
		+	FFFFFF	$+2^8 * 2^{16}$

2.3 Extended register tables

All registers can be 16 bit numbers as in ALEPH. The affected commands are:

\count	\countdef	\unhbox	\ht
\dimen	\dimendef	\unvbox	\dp
\skip	\skipdef	\сору	\setbox
\muskip	\muskipdef	\unhcopy	\vsplit
\marks	\toksdef	\unvcopy	
\toks	\box	\wd	

2.4 Attribute registers

Attributes are a completely new concept to LuaTEX. Syntactically, they behave a lot like counters: attributes obey T_EX 's nesting stack and can be used after \t etc. just like the normal \t registers.

However, there are some differences as well. Conceptually, an attribute is either set or unset. Set attributes can only have values of 0 or more, otherwise they are considered unset and automatically remapped to -1. All attributes start out in the unset state (in INITEX).

Attributes can be used as extra counter values, but their usefulness comes from the fact that the numbers and values of all set attributes are attached to all nodes created in their scope. These can then be queried from any Lua code that deals with node processing. Further information is given in the chapter on 6.

2.5 LUA related primitives

In order to merge Lua code with TFX input, a few new primitives are needed. LuaTFX has support for 65536 separate Lua interpreter states. States are automatically created based on the integer argument to the primitives \directlua and \latelua.

2.5.1 \directlua

The primitive \directlua is used to execute LuA code immediately. The syntax is

```
\directlua \langle 16-bit number \rangle \langle general text \rangle
```

The (general text) is fed into the Lua interpreter state indicated by the (16-bit number). If the state does not exist yet, then it will be initialized automatically.

This command is expandable.

2.5.2 \latelua

\latelua stores Lua code in a whatsit that will be processed inside the output routine. It's intended use is very similar to \pdfliteral.

Within the LUA code, you should use pdf.print to print stuff directly to the pdffile.

\latelua \lambda 16-bit number \rangle \lambda general text \rangle

2.5.3 \luaescapestring

This primitive converts a TFX token string so that it can be safely used as the contents of a LUA string: embedded backslashes, double quotes and single quotes are escaped by prepending an extra token consisting of a backslash with catcode 12.

\luaescapestring \langle general text \rangle

2.5.4 \closelua

This primitive allows you to close a LuA state, freeing all of its used memory.

```
\closelua \langle 16-bit number \rangle
```

You cannot close LuA state zero (0), any attempt to do so will be silently ignored.

States are only closed automatically when a fatal (out of memory) error occurs, but at that point LUATFX will exit anyway.

States are not closed immediately, but only when the output routine comes into play next (because there may be pending \latelua calls)

2.6 New ε -TEX primitives

2.6.1 \clearmarks

This primitive clears a marks class completely, resetting all three connected mark texts to empty.

\clearmarks \langle 16-bit number \rangle

2.6.2 \noligs and \nokerns

These primitives prohibit ligature and kerning insertion at the time when the initial node list is built by LUATEX's main control loop (It is a temporary trick that will be removed soon).

\noligs \langle integer \\ \nokerns \langle integer \\

2.6.3 \formatname

\formatname's syntax is identical to \jobname.

In INITEX, the expansion is empty. Otherwise, the expansion is the value that \jobname had during the INITEX run that dumped the currently loaded format.

2.6.4 \scantextokens

The syntax of \scantextokens is identical to \scantokens.

This is a slightly adapted version of ε -T_FX's \scantokens. The differences are:

- The last (and usually only) line does not have a \endlinechar appended
- \scantextokens never raises an EOF error, and it does not execute \everyeof tokens.
- The while end of file tests are not executed, allowing the expansion to end on a different grouping level or while a conditional is still incomplete

2.6.5 Catcode tables

Catcode tables are a new feature that allows you to switch to a predefined catcode regime in a single statement. You can have a practically unlimited number of different tables (at this moment up to 268.435.456. The limit depends on an array allocation).

The subsystem is backward compatible: if you never use the following commands, your document will not notice any difference in behavior compared to traditional TEX.

The contents of each catcode table is independent of any other catcode tables, and their contents is stored and retrieved from the format file.

2.6.5.1 \catcodetable

\catcodetable \langle 28-bit number \rangle

The \catcodetable switches to a different catcode table. Such a table has to be previously created using one of the two primitives below, or it has to be zero (table zero is initialized by INITEX).

2.6.5.2 \initcatcodetable

\initcatcodetable \(28\)-bit number \(\)

The \initcatcodetable creates a new table with catcodes identical to those defined by INITEX:

```
0
                          escape
    ^^M
5
                  return car_ret
   ^^@
9
                  null
                          ignore
10 <space>
                         spacer
                  space
11 \quad a-z
                          letter
11 A - Z
                          letter
12 everything else
                          other
14 %
                          comment
   ^^?
15
                  delete invalid char
```

The new catcode table is allocated globally: it will not go away after the current group has ended. If the supplied number is the currently active table, an error is raised.

2.6.5.3 \savecatcodetable

\savecatcodetable \(28\)-bit number \(\)

\savecatcodetable copies the current set of catcodes to a new table with the requested number. The definitions in this new table are all treated as if they were made in the outermost level.

The new table is allocated globally: it will not go away after the current group has ended. If the supplied number is the currently active table, an error is raised.

2.6.6 Font syntax

LUATEX will accept a braced argument as a font name:

```
font\myfont = \{cmr10\}
```

This allows for embedded spaces, without the need for double quotes. Macro expansion takes place in the argument.

3 LUA general

3.1 Initialization

3.1.1 LUATEX as a LUA interpreter

In a number of cases, LuATFX behaves like it is a LuA interpreter only.

- If a --luaonly option is given
- If the executable is named texlua (or luatexlua)
- if the non-option (file) on the commandline has the extension lua or luc.

In this mode, it will set Lua's arg[0] to the found script name, pushing preceding options in negative values and the rest of the commandline in the positive values, just like the Lua interpreter.

LUATEX will exit immediately after executing the specified LUA script and is, in effect, a somehwat bulky standalone LUA interpreter.

3.1.2 Other commandline processing

Whenever the LuaTEX executable starts, it looks for a --lua commandline option. If such an option is present, it will enter an alternative mode of commandline parsing.

In this mode, it will only interpret a very small subset of the commandline directly:

-luaonly execute a Lua script, then exit-lua=s load and execute a Lua init script

-safer disable easily exploitable LUA commands

-help display help and exit-version display version and exit

If a requested LUA script can not be found using the actual name given on the commandline, a second attempt is made by prepending the value of the environment variable LUATEXDIR, if that variable is defined.

Then the script is loaded and executed. It will find the entire commandline in the table arg, beginning with arg [0], that is the name of the executable.

LUATEX will fetch some of the other commandline options from the texconfig table at the end of script execution (see the description of the texconfig table later on in this document).

Commandline processing happens very early on. So early, in fact, that none of TEX's initializations have taken place yet. For that reason, the tex, token, node and pdf tables are off-limits during the execution of the startup file (they are nilled). Special care is taken that texio.write and texio.write nl

function properly, so that you can at least report your actions to the log file when (and if) it eventually becomes opened (note that TEX does not even know it's \jobname yet at this point).

The file is loaded into LuA state 0, and everything you do will remain visible during the rest of the run, with the exception of the tex, token, node and pdf tables: those will be restored to their normal meaning right after the execution of the script.

We recommend you use the startup file only for your own TEX-independent initializations (if you need any), to parse the commandline, set values in the texconfig table, and register the callbacks you need.

You can use the **--safer** switch to disable some commands that can easily be abused by a malicious document. At the moment, this switch **nils** the following functions:

library functions

```
os execute exec setenv rename remove
io popen output tmpfile
lfs rmdir mkdir chdir lock touch
```

And it makes io.open() fail on files that are opened for anything besides reading.

Unless the texconfig table tells it not to start KPATHSEA at all (set texconfig.kpse_init to false for that), it also acts on three other commandline options:

```
flag meaning
--fmt=s set the format name
--progname=s set the progname (only for KPATHSEA)
--ini enable INITFX mode
```

In order to initialize the built-in KPATHSEA library properly, LUATEX needs to know the correct progname to use, and for that it needs to check -progname (and -ini and -fmt, if -progname is missing).

If there is no --lua option, the commandline is interpreted in a similar fashion as in traditional PDFTEX and ALEPH.

3.2 LUA changes

Five modules that are normally external are statically linked in with LUATEX: slnunicode, luazip, luafilesystem, lpeg (version 0.6), and md5.

The read("*line") function from the io library has been adjusted so that it is line-ending neutral: any of LF, CR or CR+LF are accepted.

The tostring() printer for numbers has been changed so that it return 0 instead of something like 2e-5 (which confused TEX enormously) when the value is so small that TEX cannot distinguish it from zero.

Dynamic loading of .so and .dll files is disabled on all platforms.

luafilesystem has been extended with two extra boolean functions (isdir(filename) and isfile(filename)) and one extra string field in the attributes table (permissions).

The **string** library has six extra iterators that return strings piecemeal:

- string.utfvalues(s) (returns an integer value in the UNICODE range)
- string.utfcharacters(s) (returns a string with a single UTF-8 token in it)
- string.characters(s) (a string of length one)
- string.characterpairs(s) (two strings of length one) will produce an empty second string in the string length was odd.
- string.bytes(s) (a single byte value)
- string.bytepairs(s) (two byte values) Will produce nil instead of a number as its second return value if the string length was odd.

The os library has a few extra functions and variables:

- os.exec('command') is a non-returning version of os.execute. The advantage of this command is that it cleans out the current process before starting the new one, making it especially useful for use in TFXLUA.
- os.setenv('key', 'value') This sets a variable in the environment. Passing nil instead of a value string will remove the variable.
- os.environ This is a read-only hash table containing all of the variables and values in the process environment.

4 LUA Libraries

The interfacing between TFX and LuA is facilitated by a set of LuA modules.

4.1 The tex library

The tex table contains a large list of virtual internal TEX parameters that are partially writable.

The designation virtual means that these items are not properly defined in Lua, but are only frontends that are handled by a metatable that operates on the actual TEX values. As a result, most of the Lua table operators (like pairs and #) do not work on such items.

At the moment, it is possible to access almost every parameter that has these characteristics:

- You can use it after \the
- It is a single token.

This excludes parameters that need extra arguments, like \the\scriptfont.

The subset comprising simple integer and dimension registers are writable as well as readable (stuff like \tracingcommands and \parindent).

4.1.1 Integer parameters

The integer parameters accept and return LuA numbers.

Read-write:

tex.adjdemerits	tex.globaldefs
tex.binoppenalty	tex.hangafter
tex.brokenpenalty	tex.hbadness
tex.catcodetable	tex.holdinginserts
tex.clubpenalty	tex.hyphenpenalty
tex.day	tex.interlinepenalty
tex.defaulthyphenchar	tex.language
tex.defaultskewchar	tex.lastlinefit
tex.delimiterfactor	tex.lefthyphenmin
tex.displaywidowpenalty	tex.linepenalty
tex.doublehyphendemerits	tex.localbrokenpenalty
tex.endlinechar	tex.localinterlinepenalty
tex.errorcontextlines	tex.looseness
tex.escapechar	tex.mag
tex.exhyphenpenalty	tex.maxdeadcycles
tex.fam	tex.month
tex.finalhyphendemerits	tex.newlinechar
tex.floatingpenalty	tex.outputpenalty

tex.pausing tex.predisplaypenalty tex.pdfadjustinterwordglue tex.pretolerance tex.pdfadjustspacing tex.relpenalty tex.pdfappendkern tex.righthyphenmin tex.pdfcompresslevel tex.savinghyphcodes tex.pdfdecimaldigits tex.savingvdiscards tex.showboxbreadth tex.pdfforcepagebox tex.showboxdepth tex.pdfgamma tex.pdfgentounicode tex.time tex.pdfimageapplygamma tex.tolerance tex.pdfimagegamma tex.tracingassigns tex.pdfimagehicolor tex.tracingcommands tex.pdfimageresolution tex.tracinggroups tex.pdfinclusionerrorlevel tex.tracingifs tex.pdfminorversion tex.tracinglostchars tex.pdfmovechars tex.tracingmacros tex.pdfobjcompresslevel tex.tracingnesting tex.pdfoptionalwaysusepdfpagebox tex.tracingonline tex.pdfoptionpdfinclusionerrorlevel tex.tracingoutput tex.pdfoptionpdfminorversion tex.tracingpages tex.pdfoutput tex.tracingparagraphs tex.tracingrestores tex.pdfpagebox tex.pdfpkresolution tex.tracingscantokens tex.pdfprependkern tex.tracingstats tex.pdfprotrudechars tex.uchyph tex.pdftracingfonts tex.vbadness tex.pdfuniqueresname tex.widowpenalty tex.postdisplaypenalty tex.year tex.predisplaydirection

Read-only:

tex.deadcycles tex.parsmape tex.prevgraf tex.parshape tex.spacefactor

tex.insertpenalties

4.1.2 Dimension parameters

The dimension parameters accept Lua numbers (signifying scaled points) or strings (with included dimension). The result is always a string.

Read-write:

tex.boxmaxdepth	tex.overfullrule	tex.pdfpageheight
tex.delimitershortfall	tex.pagebottomoffset	tex.pdfpagewidth
tex.displayindent	tex.pageheight	tex.pdfpxdimen
tex.displaywidth	tex.pagerightoffset	tex.pdfthreadmargin
tex.emergencystretch	tex.pagewidth	tex.pdfvorigin
tex.hangindent	tex.parindent	tex.predisplaysize
tex.hfuzz	tex.pdfdestmargin	tex.scriptspace
tex.hoffset	tex.pdfeachlinedepth	tex.splitmaxdepth
tex.hsize	tex.pdfeachlineheight	tex.vfuzz
tex.lineskiplimit	tex.pdffirstlineheight	tex.voffset
tex.mathsurround	tex.pdfhorigin	tex.vsize
tex.maxdepth	tex.pdflastlinedepth	
tex.nulldelimiterspace	tex.pdflinkmargin	
Read-only:		
tex.pagedepth	tex.pagegoal	tex.prevdepth
tex.pagefilllstretch	tex.pageshrink	
tex.pagefillstretch	tex.pagestretch	
	and the second s	

tex.pagedepth	tex.pagegoal	tex.prevdepth
tex.pagefilllstretch	tex.pageshrink	
tex.pagefillstretch	tex.pagestretch	
tex.pagefilstretch	tex.pagetotal	

4.1.3 Direction parameters

All direction parameters are read-only and return a LuA string

tex.bodydir tex.pagedir tex.textdir tex.mathdir tex.pardir

4.1.4 Glue parameters

All glue parameters are read-only and return a LUA string

tex.abovedisplayshortskip	tex.belowdisplayskip	tex.parskip
tex.abovedisplayskip	tex.leftskip	tex.rightskip
tex.baselineskip	tex.lineskip	tex.spaceskip
tex.belowdisplayshortskip	tex.parfillskip	tex.splittopskip

```
tex.tabskip tex.xspaceskip tex.topskip
```

4.1.5 Muglue parameters

All muglue parameters are read-only and return a LUA string

```
tex.medmuskip tex.thinmuskip tex.thickmuskip
```

4.1.6 Tokenlist parameters

All tokenlist parameters are read-only and return a Lua string

tex.errhelp	tex.everyjob	tex.pdfpageattr
tex.everycr	tex.everymath	tex.pdfpageresources
tex.everydisplay	tex.everypar	tex.pdfpagesattr
tex.everyeof	tex.everyvbox	tex.pdfpkmode
tex.everyhbox	tex.output	

4.1.7 Convert commands

The supported commands at this moment are:

tex.AlephVersion	tex.eTeXVersion	tex.pdfnormaldeviate
tex.Alephrevision	tex.eTeXrevision	tex.pdftexbanner
tex.OmegaVersion	tex.formatname	tex.pdftexrevision
tex.Omegarevision	tex.jobname	

All convert commands are read-only and return a Lua string

This list looks haphazard, but it really is not. These are all the cases of the convert internal command that do not require an argument.

4.1.8 attribute, count, dimension and token registers

TEX's attributes (\attribute), counters (\count), dimensions (\dimen) and token (\toks) registers can be accessed and written to using four virtual sub-tables of the tex table:

```
tex.attribute tex.dimen tex.count tex.toks
```

It is possible to use the names of relevant \attributedef, \countdef, \dimendef, or \toksdef control sequences as indices to these tables:

```
tex.count.scratchcounter = 0
enormous = tex.dimen["maxdimen"]
```

In this case, LuaTEX looks up the value for you on the fly. You have to use a valid \countdef (or \attributedef, or \dimendef, or \toksdef), anything else will generate an error (the intent is to eventually also allow <chardef tokens> and even macros that expand into a number)

The attribute and count registers accept and return Lua numbers.

The dimension registers accept Lua numbers (in scaled points) or strings (with an included absolute dimension; em and ex and px are forbidden). The result is always a number in scaled points.

The token registers accept and return LuA strings. LuA strings are converted to token lists using \the\toks style expansion.

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setdimen(number n, string s)
tex.setdimen(string s, string s)
tex.setdimen(number n, number n)
tex.setdimen(string s, number n)
number n = tex.getdimen(number n)
number n = tex.getdimen(string s)

tex.setcount(number n, number n)
tex.setcount(string s, number n)
number n = tex.getcount(number n)
number n = tex.getcount(string s)

tex.settoks (number n, string s)
tex.settoks (string s, string s)
string s = tex.gettoks (number n)
string s = tex.gettoks (string s)
```

4.1.9 Box registers

The current dimensions of \box registers can be read and altered using three other virtual sub-tables:

```
tex.wd
tex.ht
tex.dp
```

These are indexed strictly by number.

The box size registers accept LuA numbers (in scaled points) or strings (with included dimension). The result is always a number in scaled points.

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setboxwd(number n, number n)
number n = tex.getboxwd(number n)
tex.setboxht(number n, number n)
number n = tex.getboxht(number n)
tex.setboxdp(number n, number n)
number n = tex.getboxdp(number n)
```

It is also possible to set and query actual boxes, using the node interface as defined in the node library:

```
tex.box
```

for array access, or

```
tex.setbox(number n, node s)
node n = tex.getbox(number n)
```

for function-based access

Be warned that an assignment like

```
tex.box[0] = tex.box[2]
```

does not copy the node list, it just duplicates a node pointer. If \box2 will be cleared by TEX commands later on, the contents of \box0 becomes invalid as well. To prevent this from happening, always use node.copy_list() unless you are assigning to a temporary variable:

```
tex.box[0] = node.copy_list(tex.box[2])
```

4.1.10 Print functions

The tex table also contains the three print functions that are the major interface from LuA scripting to T_EX .

The arguments to these three functions are all stored in an in-memory virtual file that is fed to the TEX scanner as the result of the expansion of \directlua.

The total amount of returnable text from a \directlua command is only limited by available system RAM. However, each separate printed string has to fit completely in TEX's input buffer.

4.1.10.1 tex.print

```
tex.print(<string s>, ...)
tex.print(<number n>, <string s>, ...)
```

Each string argument is treated by TFX as a separate input line.

The optional parameter can be used to print the strings using the catcode regime defined by \c codetable n. If n is not a valid catcode table, then it is ignored, and the currently active catcode regime is used instead.

The very last string of the very last tex.print() command in a \directlua will not have the \endlinechar appended, all others do.

4.1.10.2 tex.sprint

```
tex.sprint(<string s>, ...)
tex.sprint(<number n>, <string s>, ...)
```

Each string argument is treated by TEX as a special kind of input line that makes it suitable for use as a partial line input mechanism:

- TEX does not switch to the new line state, so that leading spaces are not ignored.
- No \endlinechar is inserted.
- Trailing spaces are not removed.

4.1.10.3 tex.write

```
tex.write(<string s>, ...)
```

Each string argument is treated by T_EX as a special kind of input line that makes is suitable for use as a quick way to dump information:

- All catcodes on that line are either space (for " ") or character (for all others).
- There is no \endlinechar appended.

4.1.11 Helper functions

4.1.11.1 tex.round

```
number n = tex.round(number o)
```

Rounds lua number o, and returns a number that is in the range of a valid TEX register value. If the number starts out of range, it generates a 'Number to big' error as well.

4.1.11.2 tex.scale

```
number n = tex.scale(number o, number delta)
table n = tex.scale(table o, number delta)
```

Multiplies the lua numbers o and delta, and returns a rounded number that is in the range of a valid TEX register value. In the table version, it creates a copy of the table with all numeric top—level values scaled in that manner. If the mutiplied number(s) are of range, it generates 'Number to big' error(s) as well.

4.2 The token library

The token table contains interface functions to TEX's handling of tokens. These functions are most useful when combined with the token_filter callback, but they could be used standalone as well.

A token is represented in LuA as a small table. For the moment, this table consists of three numeric entries:

nr	meaning	description
1	command code	this is a value between 0 and 130 (approximately)
2	command modifier	this is a value between 0 and 2^{21}
3	control sequence id	for commands that are not te result of control sequences, like letters and
		characters, it is zero, otherwise, it is number pointing into the equivalence
		table

4.2.1 token.get_next

```
token t = token.get_next()
```

This fetches the next input token from the current input source, without expansion.

4.2.2 token.is_expandable

```
boolean b = token.is_expandable(token t)
```

This tests if the token t could be expanded.

4.2.3 token.expand

```
token.expand()
```

If a token is expandable, this will expand one level of it, so that the first token of the expansion will now be the next token to be read by tex.get_next().

4.2.4 token.is_activechar

```
boolean b = token.is activechar(token t)
```

This is a special test that is sometimes handy. Discovering whether some token is the result of an active character turned out to be very hard otherwise.

4.2.5 token.create

```
token t = token.create(string csname)
token t = token.create(number charcode)
token t = token.create(number charcode, number catcode)
```

This is the token factory. If you feed it a string, then it is a control sequence csname, and it will be looked up in the equivalence table.

If you feed it number, then this is assumed to be an input character, and an optional second number gives its category code. This means it is possible to overrule a character's category code, with a few exceptions: the category codes 0 (escape), 9 (ignored), 13 (active), 14 (comment), and 15 (invalid) cannot occur inside a token. The values 0, 9, 14 and 15 are therefore illegal as input to token.create(), and active characters will be resolved immediately.

Note: unknown string sequences and never defined active characters will result in a token representing an undefined control sequence with a near-random name. It is *not* possible to define brand new control sequences using token.create!

4.2.6 token.command_name

```
string commandname = token.command_name(token t)
```

This returns the name associated with the command value of the token in LuaTEX. There is no direct connection between these names and primitives. For instance, all \ifxxx tests are grouped under if_fest, and the command modifier defines which test is to be run.

4.2.7 token.command id

```
number i = token.command name(string commandname)
```

This returns a number that is the inverse operation of the previous command, to be used as the first item in a token table.

4.2.8 token.csname_name

```
string csname = token.csname_name(token t)
```

This returns the name associated with the equivalence table value of the token in LuATEX. It returns the string value of the command used to create the current token, or an empty string if there is no associated control sequence.

4.2.9 token.csname_id

```
number i = token.csname_id(string csname)
```

This returns a number that is the inverse operation of the previous command, to be used as the third item in a token table.

4.3 The node library

The node library contains functions that facilitate dealing with (lists of) nodes and their values.

LUATEX nodes are represented in LUA as userdata with the metadata type luatex.node. The various fields within a node can be accessed using fields that are indexed by strings.

Each node has at least the three fields next, id, and subtype:

- The next field returns the userdata object for the next node in a linked list of nodes, or nil, if there is no next node.
- The id indicates TEX's node type. The field id has a numeric value for efficiency reasons, but some of the library functions also accept a string value instead of id.
- The subtype is another number. It often gives further information about a node of a particular id, but it is most important when dealing with whatsits, because they are differentiated solely based on their subtype.

The other available fields depend on the id (and for whatsits, the subtype) of the node. Further details on the various fields and their meanings are given in the chapter 6.

TEX's math nodes are not yet supported: there is not yet an interface to the internals of the math list and it is not possible to create them from Lua. Support for unset (alignment) nodes is partial: they can be queried and modified from Lua code, but not created.

Nodes can be compared to each other, but: you are actually comparing indices into the node memory. This means that equality tests can only be trusted under very limited conditions. It will not work correctly in any situation where one of the two nodes has been freed and/or reallocated: in that case, there will be false positives.

4.3.1 Node handling functions

4.3.1.1 node.types

```
table t = node.types()
```

This function returns an array that maps node id numbers to node type strings, providing an overview of the possible top-level id types.

4.3.1.2 node.whatsits

```
table t = node.whatsits()
```

TEX's whatsits all have the same id. The various subtypes are defined by their subtype. The function is much like node.id, except that it provides an array of subtype mappings.

4.3.1.3 node.id

```
number id = node.id(string type)
```

This converts a single type name to it's internal numeric representation.

4.3.1.4 node.subtype

```
number subtype = node.subtype(string type)
```

This converts a single whatsit name to it's internal numeric representation (subtype).

4.3.1.5 node.type

```
string type = node.type(number id)
```

This converts a internal numeric representation to an external string representation.

4.3.1.6 node.fields

```
table t = node.fields(string type)
table t = node.fields(string type, string subtype)
```

This function returns an array of valid field names for a particular type of node. If you want to get the valid fields for a whatsit, then you have to supply the second argument also. Otherwise, the second argument will be silently ignored.

This function accepts numeric id and subtype values as well.

4.3.1.7 node.has_field

```
boolean t = node.has_field(node n, string field)
```

This function returns a boolean that is only true if n is actually a node, and it has the field.

4.3.1.8 node.new

```
node n = node.new(string type)
node n = node.new(string type, string subtype)
```

Creates a new node. All fields are initialized to either zero or null (depending on wether the field is a number or a pointer), except for id and subtype (if supplied). If you need a new whatsit, then the second argument is required.

This function accepts numeric id and subtype values as well.

4.3.1.9 node.free

```
node.free(node n)
```

Removes the node m from TEX's memory. Be careful: no checks are done on whether this node is still pointed to from a register or some next field: it is up to you to make sure that the internal data structures remain correct.

4.3.1.10 node.flush_list

```
node.flush list(node n)
```

Removes the node list m and the complete node list following m from T_EX 's memory. Be careful: no checks are done on whether any of these nodes is still pointed to from a register or some mext field: it is up to you to make sure that the internal data structures remain correct.

4.3.1.11 node.copy

```
node m = node.copy(node n)
```

Creates a deep copy of node n. Only the next field is not copied.

4.3.1.12 node.copy_list

```
node m = node.copy_list(node n)
```

Creates a deep copy of the node list that starts at n.

4.3.1.13 node.hpack

```
node h = node.hpack(node n)
node h = node.hpack(node n, number w, string info)
```

This function creates a new hlist by packagin the list that with node n into a horizontal box. With only a single argument, this box is created using the natural width of it's components. In the three argument form, info must be either additional or exactly, and w is the additional (\hbox spread) or exact (\hbox to) width to be used.

Caveat: at this moment, there can be unintended side-effects to this function, like updating some of the \marks and \inserts.

4.3.1.14 node.slide

```
node m = node.slide(node n)
```

Returns the last node of the node list that starts at n.

4.3.1.15 node.length

```
number i = node.length(node n)
number i = node.length(node n, node m)
```

Returns the number of nodes contained in the node list that starts at n. If m is also supplied it stops at m instead of at the end of the list. The node m is not counted.

4.3.1.16 node.count

```
number i = node.count(string type, node n)
number i = node.count(string type, node n, node m)
```

Returns the number of nodes contained in the node list that starts at n that have an id matching type. If m is also supplied, counting stops at m instead of at the end of the list. The node m is not counted.

4.3.1.17 node.traverse

```
node t = node.traverse(node n)
node t = node.traverse(node n, node m)
```

This is an iterator that loops over the node list that starts at n. If m is also supplied, the iterator stops at m instead of at the end of the list. The node m is not processed.

4.3.1.18 node.traverse_id

```
node t = node.traverse_id(string type, node n, node m)
node t = node.traverse_id(string type, node n)
```

This is an iterator that loops over all the nodes in the list that starts at n that have an id matching type. If m is also supplied, the iterator stops at m instead of at the end of the list. The node m is not processed.

4.3.1.19 node.remove

```
node head, current = node.remove(node head, node current)
```

This function removes the node current from the list following head. It is your responsibility to make sure it is really part of that list. The return values are the new head and current nodes. The returned current is the node in the calling argument, and is only passed back as a convenience (it's next field will be cleared). The returned head is more important, because: if the function is called with current equal to head, it will be changed.

4.3.1.20 node.insert_before

```
node head, new = node.insert before(node head, node current, node new)
```

This function inserts the node new before current into the list following head. It is your responsibility to make sure that current is really part of that list. The return values are the (potentially mutated) head and the new, set up to be part of the list (with correct next field). If head is initially nil, it will become new.

4.3.1.21 node.insert_after

```
node head, new = node.insert_after(node head, node current, node new)
```

This function inserts the node new after current into the list following head. It is your responsibility to make sure that current is really part of that list. The return values are the head and the new, set up to be part of the list (with correct next field). If head is initially nil, it will become new.

4.3.2 Attribute handling

Attributes appear as linked list of userdata objects in the attr field of individual nodes. They can be handled individually, but it much safer and more efficient to use the dedicated functions associated with them.

4.3.2.1 node.has_attribute

```
number v = node.has_attribute(node n, number id)
number v = node.has_attribute(node n, number id, number val)
```

Tests if a node has the attribute with number id set. If val is also supplied, also tests if the value matches val. It returns the value, or, if no match is found, nil.

4.3.2.2 node.set_attribute

```
node.set_attribute(node n, number id, number val)
```

Sets the attribute with number id to the value val. Duplicate assignments are ignored.

4.3.2.3 node.unset attribute

```
number v = node.unset_attribute(node n, number id, number val)
number v = node.unset attribute(node n, number id)
```

Unsets the attribute with number id. If val is also supplied, it will only perform this operation if the value matches val. Missing attributes or attribute-value pairs are ignored.

If the attribute was actually deleted, returns its old value. Otherwise, returns nil.

4.4 The texio library

This library takes care of the low-level I/O interface.

4.4.1 Printing functions

4.4.1.1 texio.write

```
texio.write(string target, string s)
texio.write(string s)
```

Without the target argument, Writes the string to the same location(s) TEX writes messages to at this moment. If \batchmode is in effect, it writes only to the log, otherwise it writes to the log and the terminal.

The optional target can be one of three possibilities: term, log or term and log.

4.4.1.2 tex.write_nl

```
texio.write_nl(string target, string s)
texio.write_nl(string s)
```

Like texio.write, but make sure that the string s will appear at the beginning of a line. You can use an empty string if you only want to move to the next line.

4.5 The pdf library

This table contains the current h en v values that define the location on the output page. The values can be queried and set using scaled points as units.

```
pdf.v
pdf.h
```

The associated function calls are

```
pdf.setv(number n)
number n = pdf.getv()
pdf.seth(number n)
number n = pdf.geth()
```

It also holds a print function to write stuff to the PDF document, that can be used from within a \latelua argument. This function is not to be used inside \directlua unless you know exactly what you are doing.

```
pdf.print
pdf.print(<string s>)
pdf.print(<string type>, <string s>)
```

The optional parameter can be used to mimic the behaviour of \pdfliteral: the type is direct or page.

4.6 The callback library

This library has functions that register, find and list callbacks.

The callback library is only available in LuA state zero (0).

```
callback.register(string <callback name>,function <callback_func>)
callback.register(string <callback name>,nil)
```

where the (callback name) is a predefined callback name, see below.

LUATEX internalizes the callback function in such a way that it does not matter if you redefine a function accidentally.

Callback assignments are always global. You can use the special value nil instead of a function for clearing the callback.

```
table <info> = callback.list()
```

The keys in the table are the known callback names, the value is a boolean where true means that the callback is currently set (active).

```
function <f> = callback.find(<callback name>)
```

If the callback is not set, callback.find returns nil.

4.6.1 File discovery callbacks

4.6.1.1 find_read_file and find_write_file

You callback function should have the following conventions:

```
string <actual_name> = function (number <id_number>, string <asked_name>)
```

Arguments:

id number

asked_name

This is the user-supplied filename, as found by \input, \openin or \openout.

Return value:

actual_name

This is the filename used. For the very first file that is read in by TEX, you have to make sure you return an actual_name that has an extension and that is suitable for use as jobname. If you don't, you will have to manually fix the name for the log file and output file, and an eventual format filename will become mangled, since these depend on the jobname.

You have to return nil if the file cannot be found.

4.6.1.2 find font file

Your callback function should have the following conventions:

```
string <actual_name> = function (string <asked_name>)
```

The asked_name is an OTF or TFM font metrics file.

Return nil if the file cannot be found.

4.6.1.3 find_output_file

You callback function should have the following conventions:

```
string <actual_name> = function (string <asked_name>)
```

The asked_name is the PDF or DVI file for writing.

4.6.1.4 find_format_file

You callback function should have the following conventions:

```
string <actual_name> = function (string <asked_name>)
```

The asked_name is a format file for reading (the format file for writing is always opened in the current directory).

4.6.1.5 find_vf_file

Like find_font_file, but for virtual fonts. This applies to both ALEPH's OVF files and traditional Knuthian VF files.

4.6.1.6 find_ocp_file

Like find_font_file, but for ocp files.

4.6.1.7 find_map_file

Like find_font_file, but for map files.

4.6.1.8 find_enc_file

Like find_font_file, but for enc files.

4.6.1.9 find_sfd_file

Like find_font_file, but for subfont definition files.

4.6.1.10 find_pk_file

Like find_font_file, but for pk bitmap files. The argument <name> is a bit special in this case. It's form is

```
<base res>dpi/<fontname>.<actual res>pk
```

So you may be asked for 600dpi/manfnt.720pk. It is up to you to find a reasonable bitmap file to go with that specification.

4.6.1.11 find_data_file

Like find_font_file, but for embedded files (\pdfobj file "...").

4.6.1.12 find_opentype_file

Like find_font_file, but for OpenType font files.

4.6.1.13 find_truetype_file and find_type1_file

You callback function should have the following conventions:

```
string <actual_name> = function (string <asked_name>)
```

The asked_name is a font file. This callback is called while LuaTEX is building its internal list of needed font files, so the actual timing may surprise you. Your return value is later fed back into the matching read file callback.

Strangely enough, find_type1_file is also used for OpenType (otf) fonts.

4.6.1.14 find image file

You callback function should have the following conventions:

```
string <actual_name> = function (string <asked_name>)
```

The asked_name is an image file. Your return value is used to open a file from the harddisk, so make sure you return something that is considered the name of a valid file by your operating system.

4.6.2 File reading callbacks

4.6.2.1 open_read_file

You callback function should have the following conventions:

```
table <env> = function (string <file_name>)
```

Argument:

file_name

the filename returned by a previous find_read_file or the return value of kpse_find_file() if there was no such callback defined.

Return value:

env

this is a table containing at least one required and one optional callback functions for this file. The required field is **reader** and the associated function will be called once for each new line to be read, the optional one is **close** that will be called once when LuATEX is done with the file.

LUATEX never looks at the rest of the table, so you can use it to store your private per-file data. Both the callback functions will receive the table as their only argument.

4.6.2.1.1 reader

LUATEX will run this function whenever it needs a new input line from the file.

```
function(table <env>)
    return string <line>
end
```

Your function should return either a string or nil. The value nil signals that the end of file has occurred, and will make TEX call the optional close function next.

4.6.2.1.2 close

LUATEX will optionally run this function when it needs to close the file.

```
function(table <env>)
    return
end
```

Your function should not return any value.

4.6.2.2 read font file

This function is called when TEX needs to read a ofm or tfm file.

```
function(string <name>)
    return boolean <success>, string <data>, number <data_size>
end
```

success

return false when a fatal error occured (e.g. when the file cannot be found, after all).

the bytes comprising the file.

data_size

the length of the data, in bytes.

return an empty string and zero if the file was found but there was a reading problem.

4.6.2.3 read vf file

Like read_font_file, but for virtual fonts.

4.6.2.4 read_ocp_file

Like read_font_file, but for ocp files.

4.6.2.5 read_map_file

Like read_font_file, but for map files.

4.6.2.6 read enc file

Like read_font_file, but for enc files.

4.6.2.7 read sfd file

Like read_font_file, but for subfont definition files.

4.6.2.8 read_pk_file

Like read_font_file, but for pk bitmap files.

4.6.2.9 read_data_file

Like read_font_file, but for embedded files (\pdfobj file "...").

4.6.2.10 read_truetype_file

Like read_font_file, but for TRUETYPE font files. The name is a path name as returned by find_truetype_file or kpse_find_file.

4.6.2.11 read_type1_file

Like read_font_file, but for type1 font files. The name is a path name as returned by find_type1_file or kpse_find_file.

4.6.2.12 read_opentype_file

Like read_font_file, but for OpenType font files. The name is a path name as returned by find_type1_file or kpse_find_file.

4.6.3 Data processing callbacks

4.6.3.1 process_input_buffer

This callback allows you to change the contents of the line input buffer just before LUATEX actually starts looking at it.

```
function(string <buffer>)
    return string <adjusted_buffer>
end
```

If you return nil, LuaTEX will pretend like your callback never happened. You can gain a small amount of processing time from that.

4.6.3.2 token_filter

This callback allows you to change the fetch and preprocess any lexical token that enters LuaTEX, before LuaTEX executes or expands the associated command.

```
function()
    return table <token>
end
```

The calling convention for this callback is bit more complicated then for most other callbacks. The function should either return a LuA table representing a valid to-be-processed token or tokenlist, or something else like nil or an empty table.

If your LUA function does not return a table representing a valid token, it will be immediately called again, until it eventually does return a useful token or tokenlist (or until you reset the callback value to nil). See the description of token for some handy functions to be used in conjunction with this callback.

If your function returns a single usable token, then that token will be processed by LUATEX immediately. If the function returns a token list (a table consisting of a list of consecutive token tables), then that list

will be pushed to the input stack as completely new token list level, with it's token type set to inserted. In either case, the returned token(s) will not be fed back into the callback function.

4.6.4 Node list processing callbacks

The description of nodes and node lists is in the chapter 6.

4.6.4.1 buildpage_filter

This callback is called whenever LuATEX is ready to move stuff to the main vertical list. You can use this callback to do specialized manipulation of the page building stage like imposition or column balancing.

```
function(node <head>)
    return true | false | node <newhead>
end
```

As for all the callbacks that deal with nodes, the return value can be one of three things:

- boolean true signals successful processing
- node signals that the head node should be replaced by this node
- boolean false signals that the head node list should be ignored and flushed from memory

4.6.4.2 pre_linebreak_filter

This callback is called just before LuaTEX starts converting a list of nodes into a stack of \hboxes. The removal of any final skip and the subsequent insertion of \parfillskip has not happened yet at that moment.

```
function(node <head>, string <groupcode>, int <glyph_count>)
   return true | false | node <newhead>
end
```

The string called groupcode identifies the nodelist's context within TEX's processing. The range of possibilities is given in the table below, but not all of those can actually appear in pre_linebreak_filter, some are for the Xpack_filter callbacks that will be explained in the next two paragraphs.

value	explanation
hbox	\hbox in horizontal mode
adjusted_hbox	\hbox in vertical mode
vbox	\vbox
vtop	\vtop
align	\halign or \valign
disc	discretionaries
insert	packaging an insert

```
vcenter
local_box
split_off
split_keep
preamble
align_set
fin row
\localleftbox or \localrightbox
stop of a \vsplit
remainder of a \vsplit
alignment preamble
alignment cell
alignment row
```

4.6.4.3 hpack_filter

This callback is called when T_EX is ready to start boxing some horizontal mode material. Math items are ignored at the moment.

The packtype is either additional or exactly. If additional, then the size is a \hbox spread ... argument. If exactly, then the size is a \hbox to In both cases, the number is in scaled points.

4.6.4.4 vpack_filter

This callback is called when TEX is ready to start boxing some vertical mode material. Math displays are ignored at the moment.

This function is very similar to the $hpack_filter$. Besides the fact that it is called at different moments, there is an extra variable that matches $T_EX's \rightarrow b$ but there is no glyph count.

4.6.4.5 pre_output_filter

This callback is called when TFX is ready to start boxing the box 255 for \output.

4.6.5 Information reporting callbacks

```
4.6.5.1 start_run
```

```
function()
```

Replaces the code that prints LuaTEX's banner

4.6.5.2 stop_run

```
function()
```

Replaces the code that prints LuATEX's statistics and output written to messages.

4.6.5.3 start_page_number

```
function()
```

Replaces the code that prints the [and the page number at the begin of \shipout. This callback will also override the printing of box information that normally takes place when \tracingoutput is positive.

4.6.5.4 stop_page_number

```
function()
```

Replaces the code that prints the] at the end of \shipout

4.6.5.5 show_error_hook

```
function()
    return
end
```

This callback is run from inside the TEX error function, and the idea is to allow you to do some extra reporting on top of what TEX already does (none of the normal actions are removed). You may find some of the values in the status table useful.

```
message
```

is the formal error message $T_E X$ has given to the user (the line after the "!") indicator

is either a filename (when it is a string) or a location indicator (a number) that can means lots of different things like a token list id or a \read number.

lineno

is the current line number

This is an investigative item only, only for 'testing the water'.

The final goal is the total replacement of T_EX's error handling routines, but that needs lots of adjustments in the web source because T_FX deals with errors in a somewhat haphazard fashion.

4.6.6 Font-related callbacks

```
4.6.6.1 define_font
```

```
function(string <name>, number <size>, number <id>)
    return table <font>
end
```

The string <name> is the filename part of the font specification, as given by the user.

The number <size> is a bit special:

- if it is positive, it specifies an at size in scaled points.
- if it is negative, its absolute value represents a scaled setting relative to the designsize of the font.

The internal structure of the table that is to be returned is explained in chapter 5. That table is saved internally, so you can put extra fields in the table for your later LuA code to use.

4.7 The lua library

This library contains two read-only items:

4.7.1 Variables

```
number n = lua.id
```

This sets the id number of the instance.

```
string s = lua.version
```

This sets a LuaTEX version identifier string (currently "0.1").

4.7.2 LUA bytecode registers

Lua registers can be used to communicate Lua functions across Lua states. The accepted values for assignments are functions and nil. Likewise, the retrieved value is either a function or nil.

```
lua.bytecode[n] = function () .. end
lua.bytecode[n]()
```

The contents of the lua.bytecode array is stored inside the format file as actual Lua bytecode, so it can also be used to preload lua code.

The associated function calls are

```
function f = lua.getbytecode(number n)
lua.setbytecode(number n, function f)
```

4.8 The kpse library

4.8.1 kpse.find_file

The most important function in the library is find_file:

```
string f = kpse.find_file(string filename)
string f = kpse.find_file(string filename, string ftype)
string f = kpse.find_file(string filename, boolean mustexist)
string f = kpse.find_file(string filename, string ftype, boolean mustexist)
string f = kpse.find_file(string filename, string ftype, number dpi)
```

Arguments:

filename

the name of the file you want to find, with or without extension.

type

```
maps to the -format argument of KPSEWHICH. The supported values are:
```

```
gf
                                          fmt
pk
                                          map
bitmap font
                                          mem
tfm
                                          mf

                                               web
   tex
                                               cweb
   TeX system documentation
                                               enc files
                                               cmap files
   texpool
   TeX system sources
                                               subfont definition files
  PostScript header
                                               opentype fonts
   Troff fonts
                                               pdftex config
   type1 fonts
                                               lig files
                                               texmfscripts
   vf
   dvips config
   truetype fonts
   The default type is tex.
mustexist
   is similar to KPSEWHICH'S -must-exist, and the default is false. If you specify true (or a non-
   zero integer), then the KPSE library will search the disk as well as the ls-R databases.
dpi
```

This is used for the size argument of the formats pk, gf, and bitmap font.

4.8.2 kpse.set_program_name

Sets the KPATHSEA executable (and optionally program) name

```
kpse.set_program_name(string name)
kpse.set_program_name(string name, string progname)
```

The second argument controls the use of the dotted values in the texmf.cnf configuration file, and defaults to the first argument.

4.8.3 kpse.init_prog

Extra initialization for programs that need to generate bitmap fonts.

```
kpse.init_prog(string prefix, number base_dpi, string mfmode)
kpse.init_prog(string prefix, number base_dpi, string mfmode, string fall-back)
```

4.8.4 kpse.readable_file

Test is a (absolute) file name is a readable file

```
string f = kpse.readable_file(string name)
```

The return value is the actual absolute filename you should use, because the disk name is not always the same as the requested name, due to aliases and system-specific handling under e.g. MSDOS.

Returns nil if the file does not exist or is not readable.

4.8.5 kpse.expand_path

```
Like kpsewhich's -expand-path:
```

```
string r = kpse.expand_path(string s)
```

4.8.6 kpse.expand_var

```
Like kpsewhich's -expand-var:
```

```
string r = kpse.expand_var(string s)
```

4.8.7 kpse.expand_braces

```
Like kpsewhich's -expand-braces:
```

```
string r = kpse.expand_braces(string s)
```

4.8.8 kpse.var_value

```
Like kpsewhich's -var-value:
```

```
string r = kpse.var value(string s)
```

4.9 The status library

This contains a number of run-time configuration items that you may find useful in message reporting, as well as an iterator function that gets all of the names and values as a table.

```
table <info> = status.list()
```

The keys in the table are the known items, the value is the current value.

Almost all of the values in status are fetched through a metatable at run-time whenever they are accessed, so you cannot use pairs on status, but you can use pairs on <info>, of course.

If you do not need the full list, you can also ask for a single item by using it's name as an index into status.

The current list is:

keyexplanationpdf_gonewritten PDF bytespdf_ptrnot yet written pdf bytesdvi_gonewritten dvi bytesdvi_ptrnot yet written dvi bytestotal_pagesnumber of written pages

total_pages number of written pages
output_file_name name of the PDF or DVI file

lasterrorstring last error string

luastates number of active LuA interpreters

4.10 The texconfig table

This is a table that is created empty. A startup LuA script could fill this table with a number of settings that are read out by the executable after loading and executing the startup file.

key	type	default	explanation
pool_size	number	100000	cf. web2c docs
string_vacancies	number	75000	cf. web2c docs
<pre>pool_free</pre>	number	5000	cf. web2c docs

			this key will be tested first instead of simply quitting
jobname	string		If no input file name was given on the command- line, this key will be tested first instead of simply giving up

4.11 The font library

The font library will provide the interface into the internals of the font system, as well as contain some binary font loaders.

4.11.1 Loading a TFM file

table fnt = font.read_tfm(string name, number s)

The number is a bit special:

- if it is positive, it specifies an at size in scaled points.
- if it is negative, its absolute value represents a scaled setting relative to the designsize of the font.

The internal structure of the virtual font table that is returned is explained in chapter 5.

4.11.2 Loading a VF file

```
table vf_fnt = font.read_vf(string name, number s)
```

The number is a bit special:

- if it is positive, it specifies an at size in scaled points.
- if it is negative, its absolute value represents a scaled setting relative to the designsize of the font.

4.11.3 Loading an OPENTYPE or TRUETYPE file

If you want to use an OpenType font, you have to get the metric information from somewhere. The next two functions provide a way of doing that.

```
table ttf_metrics = font.read_otf(string filename)
table ttf_metrics = font.read_ttf(string filename)
```

The result is identical in both cases, but you have to use the read_otf for loading of information from PostScript-based OpenType and read_ttf for loading of TrueType-based OpenType (or simply a TrueType font). Bitmap-only OpenType fonts are not supported.

At the moment, the filename font file is actually parsed and even partially interpreted by the OpenType/TrueType loading routines from FontForge. There are a few reasons for this:

- The font is automatically re-encoded, so that the ttf_metrics table is using UNICODE for the character indices.
- Many features are pre-processed into a format that is easier to handle than just the bare tables would be.
- PostScript-based OpenType fonts do not store the character height and depth in the font file, so the actual character boundingbox has to be calculated.
- In the future, it may be interesting to allow LUA scripts access to the actual font programs.

The top-level keys in the returned table are (this documentation is not yet finished):

key	type	explanation
table_version	number	<pre>indicates the read_otf() version</pre>
fontname	string	
fullname	string	
familyname	string	
weight	string	
copyright	string	
filename	string	
defbasefilename	string	
version	string	
italicangle	float	
upos	float	

uwidth float units_per_em number number ascent descent number vertical_origin number uniqueid number number glyphcnt glyphmax number glyphs array changed number hasvmetrics number order2 number strokedfont number weight_width_slope_only number head_optimized_for_cleartype number uni_interp enum

unset, none, adobe, greek, japanese, trad_chinese, simp_chinese, korean, ams

number
float
number
array
array
number
table

4.11.3.1 Glyph items

The glyphs is an array containing the per-character information (quite a few of these are only present if nonzero).

key	type	explanation
name	string	
unicodeenc	number	
boundingbox	array	array of four numbers
width	number	(only for horizontal fonts)
vwidth	number	(only for vertical fonts)
lsidebearing	number	(only if nonzero)
${\tt glyph_class}$	number	(only if nonzero)
kerns	array	(only for horizontal fonts, if set)
vkerns	array	(only for vertical fonts, if set)
dependents	array	linear array of glyph name strings (only if nonempty)
possub	table	(only if nonempty)
ligofme	table	(only if nonempty)
comment	string	(only if set)
color	number	(only if set)
tex_height	number	(only if set)
tex_depth	number	(only if set)
tex_sub_pos	number	(only if set)
tex_super_pos	number	(only if set)

The kerns and vkerns are linear arrays of small hashes:

key	type	explanation
char	string	
off	number	
sli	number	
flags	number	

The possub is a linear array of small hashes:

key	type	explanation
type	enum	position, pair, substitution, alternate, multiple, ligature, lcaret, kerning, vkerning, anchors, contextpos, contextsub,
		chainpos, chainsub, reversesub, max, kernback, vkernback
flags	number	
tag	string	
script_lang_index	number	

For the first seven values of type, there can be additional sub-information:

value	key	type	explanation
position	pos	table	vr table
pair	pair	table	one string: paired, and a vr (sub)table
substitution	subs	table	one string: variant
alternate	alt	table	one string: components
multiple	mult	table	one string: components
ligature	lig	table	two strings: components, char
lcaret	lcaret	array	linear array of numbers

The vr table contains for number-valued fields: xoff, yoff, h_adv_off and v_adv_off.

The other values of type could probably use some extra information as well, but I do not know which case of the union is supposed to be selected.

The ligofme is a linear array of small hashes:

key	type	explanation
lig	table	uses the same substructure as a single possub item
char	string	
components	array	linear array of named components
ccnt	number	

4.11.3.2 map table

The top-level map is a list of encoding mappings. Each of those is a table itself.

key	type	explanation
enccount	number	
encmax	number	
backmax	number	
remap	table	
map	array	non-linear array of mappings
backmap	array	non-linear array of backward mappings
enc	table	

The remap table is very small:

key	type	explanation
firstenc	number	
lastenc	number	
infont	number	

The enc table is a bit more verbose:

key	type	explanation
enc_name	string	
char_cnt	number	
char_max	number	
unicode	array	of Unicode position numbers
psnames	array	of PostScript glyph names
builtin	number	
hidden	number	
only_1byte	number	
has_1byte	number	
has_2byte	number	
is_unicodebmp	number	(only if nonzero)
is_unicodefull	number	(only if nonzero)
is_custom	number	(only if nonzero)
is_original	number	(only if nonzero)
is_compact	number	(only if nonzero)
is_japanese	number	(only if nonzero)
is_korean	number	(only if nonzero)
is_tradchinese	number	(only if nonzero)
is_simplechinese	number	
low_page	number	
high_page	number	
iconv_name	string	
iso_2022_escape	string	

4.11.3.3 private table

This is the font's private PostScript dictionary, if any. Keys and values are both strings.

4.11.3.4 cidinfo table

registry string ordering string supplement number version number

4.11.3.5 pfminfo table

The ${\tt pfminfo}$ table contains most of the OS/2 information:

key	type	explanation
pfmset	number	
winascent_add	number	
windescent_add	number	
hheadascent_add	number	
hheaddescent_add	number	
typoascent_add	number	
typodescent_add	number	
subsuper_set	number	
panose_set	number	
hheadset	number	
vheadset	number	
pfmfamily	number	
weight	number	
width	number	
avgwidth	number	
firstchar	number	
lastchar	number	
fstype	number	
linegap	number	
vlinegap	number	
hhead_ascent	number	
hhead_descent	number	
hhead_descent	number	
os2_typoascent	number	
os2_typodescent	number	
os2_typolinegap	number	
os2_winascent	number	
os2_windescent	number	
os2_subxsize	number	
os2_subysize	number	
os2_subxoff	number	
os2_subyoff	number	
os2_supxsize	number	
os2_supysize	number	
os2_supxoff	number	
os2_supyoff	number	
os2_strikeysize	number	
os2_strikeypos	number	
os2_family_class	number	
os2_xheight	number	

```
os2_capheight number
os2_defaultchar number
os2_breakchar number
os2_vendor string
panose table
```

The panose subtable has exactly 10 string keys:

	key	type
familytype	string	Values as in the OpenType font specification: Any, No Fit, Text and Display, Scri
serifstyle	string	See the OpenType font specification for values
weight	string	id.
proportion	string	id.
contrast	string	id.
strokevariation	string	id.
armstyle	string	id.
letterform	string	id.
midline	string	id.
xheight	string	id.

4.11.3.6 names table

Each item has two top-level keys:

```
key type explanation lang string language for this entry names table
```

The names keys are the actual TrueType name strings. The possible keys are:

key	type	explanation
copyright		
family		
subfamily		
uniqueid		
fullname		
version		
postscriptname		
trademark		
manufacturer		
designer		
descriptor		
venderurl		
designerurl

4.11.4 Loading OPENTYPE or TRUETYPE name information

```
table ttf_info = font.read_otf_info(string name)
table ttf_info = font.read_ttf_info(string name)
```

These two functions are very similar to the two commands from previous section, but they only return a small subset of the information. The returned table only has five keys: fontname, fullname, familyname, weight and table_version.

4.11.5 The fonts array

```
font.fonts[n] = { ... }
table f = font.fonts[n]
```

See chapter 5 for the structure of the tables.

The associated function calls are

```
table f = font.getfont(number n)
font.setfont(number n, table f)
```

Note the following: Assignments can only be made to fonts that have already be defined in TEX, but have not been accessed *at all* since that definition. This limits the usability of the write access to font.fonts quite a lot, a less stringent ruleset will be implemented later.

4.11.6 Checking a font's status

You can test for the status of a font by calling this function:

```
boolean f = font.frozen(number n)
```

The return value is one of true (unassignable), false (can be changed) or nil (not a valid font at all).

4.11.7 Defining a font directly

You can define your own font into font.fonts

```
number i = font.define(table f)
```

The return value is the internal id number of the defined font (the index into font.fonts). If the font creation fails, an error is raised. The table is a font structure, as explained in chapter 5.

4.11.8 Currently active font

```
number i = font.currentid;
```

This is the currently used font number.

5 Font structure

All TEX fonts are represented to Lua code as tables, an internally as C structures. All keys in the table below are saved in the internal font structure if they are present in the table returned by the define_font callback, or if they result from the normal TFM/VF reading routines if there is no define_font callback defined.

The column from VF means that this key will be created by the font.read_vf() routine, from TFM means that the key will be created by the font.read_tfm() routine, and used means whether or not the LuaTEX engine itself will do something with the key.

The top-level keys in the table are as follows:

key	from vf	from tfm	used	value type	description
name	yes	yes	yes	string	metric (file) name
area	no	yes	yes	string	(directory)location, typically empty
used	no	yes	yes	boolean	used already? (initial: false)
characters	yes	yes	yes	table	the defined glyphs of this font
checksum	yes	yes	no	number	default: 0
designsize	no	yes	yes	number	expected size (default: $655360 == 10pt$)
direction	no	yes	yes	number	default: 0 (LTR)
encodingbytes	no	no	yes	number	default: depends on format
encodingname	no	no	yes	string	encoding name
fonts	yes	no	yes	table	locally used fonts
fullname	no	no	yes	string	actual (PostScript) name
header	yes	no	no	string	header comments, if any
hyphenchar	no	no	yes	number	default: TeX's \hyphenchar
parameters	no	yes	yes	hash	default: 7 parameters, all zero
size	no	yes	yes	number	loaded (at) size. (default: same as designsize)
skewchar	no	no	yes	number	default: TeX's \skewchar
type	yes	no	yes	string	basic type of this font
format	no	no	yes	string	disk format type
embedding	no	no	yes	string	PDF inclusion
filename	no	no	yes	string	disk file name

The key name is always required.

The key used is set by the engine when a font is actively in use, this makes sure that the font's definition is written to the output file (DVI or PDF). The TFM reader sets it to false.

The direction is a number signalling the normal direction for this font. There are sixteen possibilities:

number	meaning	number	meaning
0	LT	8	TT
1	LL	9	TL
2	LR	10	TR

3	LR	11	TR
4	RT	12	BT
5	RL	13	BL
6	RB	14	BB
7	RR	15	BR

These are OMEGA-style direction abbreviations: the first character indicates the first edge of the character gluphs (the edge that is seen first in the writing direction), the second the top side.

The parameters is a hash with mixed key types. There are seven possible string keys, as well as a number of integer indices (these start from 8 up). The seven strings are actually used instead of the bottom seven indices, because that gives a nicer user interface.

The names and their internal remapping:

name	internal remapped number
slant	1
space	2
space_stretch	3
space_shrink	4
x_height	5
quad	6
extra_space	7

The keys type, format, embedding, fullname and filename are used to embed OpenType fonts in the result PDF.

The characters table is a list of character hashes indexed by integer number. The number is the internal code. TFX knows this character by.

Two very special string indexes can be used also: left_boundary is a virtual character whose ligatures and kerns are used to handle word boundary processing. right_boundary is similar but not actually used for anything (yet!).

Other index keys are ignored.

Each character hash itself is a hash. For example, here is the character f (decimal 102) in the font cmr10 at 10 points:

```
[102] = {
    ["kerns"] = {
        [63] = 50973,
        [93] = 50973,
        [39] = 50973,
        [33] = 50973,
        [41] = 50973
    },
    ["italic"] = 50973,
    ["height"] = 455111,
```

```
["depth"] = 0,
  ["ligatures"] = {
    [102] = {
       ["char"] = 11,
       ["type"] = 0
    },
    [108] = {
       ["char"] = 13,
       ["type"] = 0
    },
    [105] = {
       ["char"] = 12,
       ["type"] = 0
    }
  },
  ["width"] = 200250
}
```

The following top-level keys can be present inside a character hash:

key	from vf	from tfm	used	value type	description
width	yes	yes	yes	number	character's width, in sp (default 0)
height	no	yes	yes	number	character's height, in sp (default 0)
depth	no	yes	yes	number	character's depth, in sp (default 0)
italic	no	yes	yes	number	character's italic correction, in sp (default zero)
next	no	yes	yes	number	the next larger character index
extensible	no	yes	yes	table	the constituent bits of an extensible recipe
kerns	no	yes	yes	table	kerning information
ligatures	no	yes	yes	table	ligaturing information
commands	yes	no	yes	array	virtual font commands
name	no	no	no	string	the character (PostScript) name
index	no	no	yes	number	the (OPENTYPE or TRUETYPE) font glyph index
used	no	yes	yes	boolean	typeset already (default: false)?

The presence of extensible will overrule next, if that is also present.

The extensible table is very simple:

```
key
     type
              description
              top character index
top
     number
     number
              middle character index
mid
bot
     number
              bottom character index
rep
     number
              repeatable character index
```

The kerns table is a hash indexed by character index (and character index is defined as either a nonnegative integer or the string value right_boundary), with the values the kerning to be applied, in scaled points.

The ligatures table is a hash indexed by character index (and character index is defined as either a non-negative integer or the string value right_boundary), with the values being yet another small hash, with two fields:

key type description type number the type of this ligature command, default 0 char number the character index of the resultant ligature

The char field in a ligature is required.

The type field inside a ligature is the numerical or string value of one of the eight possible ligature types supported by TEX. When TEX inserts a new ligature, it puts the new glyph in the middle of the left and right glyphs. The original left and right glyphs can optionally be retained, and when at least one of them is kept, it is also possible to move the new insertion point forward one or two places. The glyph that ends up to the right of the insertion point will become the next left.

textual (Knuth)	number	string	result
l + r =: n	0	=:	n
l + r =: n	1	=:	nr
l + r =: n	2	=:	ln
l + r = n	3	=:	lnr
l + r =: > n	5	=: >	n r
l + r = > n	6	=:>	l n
l + r = > n	7	=: >	l nr
l + r = > n	11	=: >>	ln r

The default value is 0, and can be left out. That signifies a normal ligature where the ligature replaces both original glyphs. In this table the | indicates the final insertion point.

The commands array is explained below.

5.1 Real fonts

Whether or not a TEX font is a real font that should be written to the PDF document is decided by the type value in the top-level font structure. If the value is real, then this is a proper font, and the inclusion mechanism will attempt to add the needed font object definitions to the PDF.

Values for type:

value description real this is a base font virtual this is a virtual font

The actions to be taken depend on a number of different variables:

- Whether the used font fits in an 8-bit encoding scheme or not
- The type of the disk font file
- The level of embedding requested

A font that uses anything other than an 8-bit encoding vector has to be written to the PDF in a different way.

The rule is: if the font table has encodingbytes set to 2, then this is a wide font, in all other cases it isn't. The value 2 is the default for OpenType and TrueType fonts loaded via Lua.

If no special care is needed, LuaTEX currently falls back to the mapfile-based solution used by PDFTEX and DVIPS. This behaviour will be removed in the future, when the existing code becomes integrated in the new subsystem.

But if this is a wide font, then the new subsystem kicks in, and some extra fields have to be present in the font structure. In this case, LuAT_FX does not use a map file at all.

The extra fields are: format, embedding, fullname, cidinfo (as explained above), filename, and the index key in the separate characters.

Values for format:

value description
type1 this is a PostScript Type1 font
type3 this is a bitmapped (PK) font
truetype this is a TrueType or TrueType-based OpenType font
opentype this is a PostScript-based OpenType font

Curerntly, only TrueType and OpenType fonts can be wide fonts (Type1 PostScript fonts are not supported).

Values for embedding:

value description

no don't embed the font at all

subset include and atttempt to subset the font

full include this font in it's entirety

At the moment, subset only works for PostScript-based non-cid OpenType fonts, every other font format essentially is treated as full.

It is not possible to artificially modify the transformation matrix for the font at the moment.

The other fields are used as follows: The fullname will be the PostScript/PDF font name. The cidinfo will be used as the character set (the CID /Ordering and /Registry keys). The filename points to the actual font file. If you include the full path in the filename or if the file is in the local directory, LUATEX will run a little bit more efficient because it will not have to re-run the find_xxx_file callback in that case.

Be careful: when mixing old and new fonts in one document, it is possible to create name PostScript name clashes that can result in printing errors. When this happens, you have to change the fullname of the font.

Typeset strings are written out in a wide format using 2 bytes per glyph, using the index key in the character information as value. The overall effect is like having an encoding based on numbers instead of traditional (PostScript) name-based reencoding.

This type of reencoding means that there is no longer a clear connection between the text in your input file and the strings in the output PDF file. Dealing with this is on the agenda.

5.2 Virtual fonts

You have to take the following steps if you want LUATEX to treat the returned table from define_font as a virtual font:

- Set the top-level key type to virtual.
- Make sure there is at least one valid entry in fonts (see below)
- Give a commands array to every character (see below)

The presence of the toplevel type key with the specific value virtual will trigger handling of the rest of the special virtual font fields in the table, but the mere existence of 'type' is enough to prevent LuaTEX from looking for a virtual font on its own.

Therefore, this also works in reverse: if you are absolutely certain that a font is not a virtual font, assigning the value base or real to type will inhibit LUATEX from looking for a virtual font file, thereby saving you a disk search.

The fonts is another Lua array. The values are one- or two-key hashes themselves, each entry indicating one of the base fonts in a virtual font. An example makes this easy to understand

says that the first referenced font (index 1) in this virtual font is ptrmr8a loaded at 10pt, and the second is psyr loaded at a little over 9pt. The third one is previously defined font that is known to LuaTeX as fontid 38.

The array index numbers are used by the character command definitions that are part of each character.

The commands array is a hash here each item is another small array, with first entry representing a command and the extra items the parameters to that command. The allowed commands and their arguments are:

command name	arguments	arg type	description
font	1	number	select a new font from the local fonts table
char	1	number	typeset this character number from the current
node	1	node	output this node (list), and move right
slot	2	number	a shortcut for a font, char set
push	0		save current position
nop	0		do nothing
pop	0		pop position
rule	2	2 numbers	output a rule $w * h$, and move right
down	1	number	move down on the page

```
right 1 number move right on the page
special 1 string output a \special command
comment any any the rest of the command is ignored
```

Here is a rather elaborate example:

```
commands = {
  {"push"},
                                 -- remember where we are
  {"right", 5000},
                                 -- move right about 0.08pt
  {"font", 1},
                                 -- select the fonts[1] entry
  {"char", 97},
                                 -- place character 97 (a)
  {"pop"},
                                 -- go all the way back
  {"down", -200000},
                                 -- move *up* about 3pt
  {"special", "pdf: 1 0 0 rg"}
                                 -- switch to red color
  {"rule", 500000, 20000}
                                 -- draw a bar
  {'special', "pdf: 0 g"}
                                 -- back to black
}
```

The default value for font is always 1, for each character anew. If the virtual font is essentially only a re-encoding, then you do usually do not have create an explicit font entry.

Regardless of the amount of movement you create within the commands, the output pointer will always move by exactly the width as given in the width key of the character hash, after running the commands.

Even in a real font, there can be virtual characters. When LuATEX encounters a commands field inside a character when it becomes time to typeset the character, it will interpret the commands, just like for a true virtual character. In this case, if you have created no fonts array, then the default and only base font is taken to be the current font itself. In practise, this means that you can create virtual duplicates of existing characters.

Note: this feature does *not* work the other way around. There can not be real characters in a virtual font!

Finally, here is a plain TEX input file with a demonstration:

```
% start of virtual-demo.tex

\pdfoutput=1
\directlua0 {
   callback.register("define_font",
     function (name, area, size)
     if name == 'cmr10-red' then
        f = font.read_tfm('cmr10', size)
        f.name = 'cmr10-red'
        f.type = 'virtual'
        f.fonts = {{'cmr10', size}}
```

```
for i,v in pairs(f.characters) do
          if (string.char(i)):find("[tacohanshartmut]") then
            v.commands = {
              {'special','pdf: 1 0 0 rg'},
              {'char',i},
              {'special','pdf: 0 g'},
            }
          else
            v.commands = {{'char',i}}
          end
        end
      else
        f = font.read_tfm(name,size)
      return f
    end
  )
}
\font\myfont = cmr10-red \myfont This is a line of text \par
\font\myfontx= cmr10 \myfontx Here is another line of text \par
\bye
\% end of virtual-demo.tex
```

6 Nodes

6.1 LUA node representation

T_FX's nodes are represented in LuA as userdata object with a variable set of fields.

The current return value of node.types() is: vlist (1), rule (2), ins (3), mark (4), adjust (5), disc (7), whatsit (8), math (9), glue (10), kern (11), penalty (12), unset (13), style (14), choice (15), ord (16), op (17), bin (18), rel (19), open (20), close (21), punct (22), inner (23), radical (24), fraction (25), under (26), over (27), accent (28), vcenter (29), left (30), right (31), action (39), margin_kern (40), glyph (41), attribute (42), glue_spec (43), attribute_list (44), hlist (0), but as already mentioned, the math and alignment nodes in this list are not supported at the moment. The useful list is described in the next sections.

6.1.1 Auxiliary items

A few node-typed userdata objects do not occur in the normal list of nodes, but can be pointed to from within that list. They are not quite really nodes, but it is easier for the library routines to treat them as if they were.

6.1.1.1 glue_spec items

Skips are about the only type of data objects in traditional TEX that are not a simple value. The structure that represents the glue components of a skip is called a glue_spec, and it has the following accessible fields:

key	type	explanation
width	number	
stretch	number	
stretch_order	number	
shrink	number	
shrink_order	number	

These objects are reference counted, so there is actually an extra field named ref_count as well, but that will become completely hidden in the near future.

6.1.1.2 attribute_list items

The newly introduced attribute registers are also non-trivial, because the value that is attached to a node is essentially a sparse array of key-value pairs.

It is generally easiest to deal with attributes by using the dedicated functions in the node library, but for completeness, here is the low-level interface:

field type explanation

next node pointer to the first attribute

There are no extra fields, this kind of item is only used as a head pointer for attribute items, making them easier to handle.

A normal node's attribute field will point to a field of this type, and the next field in that field will then point to the first defined attribute item, whose next will point to the second attribute item, etc.

6.1.1.3 attribute item

Valid fields:

field	type	explanation
next	node	pointer to the next attribute
number	number	the LHS
value	number	the RHS

6.1.2 Main text nodes

These are the nodes that comprise actual typesetting commands.

A few fields are present in all nodes regardless of their type, these are:

field	type	explanation
next	node	The next node in a list, or nil
id	number	The node's type (id) number
subtype	number	The node subtype identifier

The subtype is sometimes just a stub entry. Almost all nodes also have an attr field. In the following tables next and id are not explicitly mentioned.

6.1.2.1 hlist nodes

Valid fields: attr, width, depth, height, dir, shift, glue_order, glue_sign, glue_set, list

field	type	explanation
subtype	number	unused
attr	node	The head of the associated attribute list
width	number	
height	number	
depth	number	
shift	number	a displacement perpendicular to the character progression direction
glue_order	number	a number in the range 0–4, indicating the glue order
glue_set	number	the calculated glue ratio

glue_sign number

6.1.2.2 vlist nodes

Valid fields: As for hlist, except that shift is a displacement perpendicular to the line progression direction.

6.1.2.3 rule nodes

Valid fields: attr, width, depth, height, dir

field explanation type subtype number unused attr node width number Rule size. The special value -1073741824 is used for running glue dimensions height number depth number number the direction of this rule dir

6.1.2.4 ins nodes

Valid fields: attr, cost, depth, height, top_skip, list

field explanation type number the insertion class subtype attr node cost number The penalty associated with this insert number height depth number list node the body of this insert a pointer to the \splittopskip glue spec top_skip node

6.1.2.5 mark nodes

Valid fields: attr, class, mark

field type explanation
subtype number unused
attr node
class number the mark class
mark table a table representing a token list

6.1.2.6 adjust nodes

Valid fields: attr, list

 $\begin{array}{lll} \mbox{field} & \mbox{type} & \mbox{explanation} \\ \mbox{subtype} & \mbox{number} & 1 = \mbox{pre} \\ \end{array}$

attr node

list node adjusted material

6.1.2.7 disc nodes

Valid fields: attr, pre, post, replace

field type explanation
subtype number unused

attr node

pre node pointer to the pre-break text
post node pointer to the post-break text

replace number the number of nodes to skip if this discretionary is chosen as a breakpoint

6.1.2.8 math nodes

Valid fields: attr, surround

field type explanation subtype number 0 = on, 1 = off

attr node

surround number width of the \mathsurround kern

6.1.2.9 glue nodes

Valid fields: attr, spec, leader

field type explanation

subtype number $0 = \$ internal glue parameters, $100 = \$ leaders, $101 = \$

attr node

spec node pointer to a glue_spec item

leader node pointer to a box or rule for leaders

6.1.2.10 kern nodes

Valid fields: attr, kern

```
\begin{array}{lll} \textbf{field} & \textbf{type} & \textbf{explanation} \\ \textbf{subtype} & \textbf{number} & 0 = \textbf{from font}, \, 1 = \textbf{from \kern or \label{eq:contact}} \\ \textbf{attr} & \textbf{node} \\ \textbf{width} & \textbf{number} \end{array}
```

6.1.2.11 penalty nodes

```
Valid fields: attr, penalty

field type explanation
subtype number not used
attr node
penalty number
```

6.1.2.12 glyph nodes

Valid fields: attr, char, font, components

6.1.2.13 margin_kern nodes

```
Valid fields: attr, width, glyph

field type explanation
subtype number 0 = left side, 1 = right side
attr node
width number
glyph node
```

6.1.3 whatsit nodes

Whatsit nodes come in many subtypes, that you can ask for my running node.whatsits(): write (1), close (2), special (3), language (4), local_par (6), dir (7), pdf_literal (8), pdf_refobj (10), pdf_refxform (12), pdf_refximage (14), pdf_annot (15), pdf_start_link (16), pdf_end_link (17), pdf_dest (19), pdf_thread (20), pdf_start_thread (21), pdf_end_thread (22), pdf_save_pos (23), pdf_restore (45), pdf_snap_ref_point (34), open (0), late_lua

(38), pdf_colorstack (42), pdf_save (44), user_defined (46), pdf_snapy (35), close_lua (39), pdf_setmatrix (43), pdf_snapy_comp (36),

6.1.3.1 open nodes

Valid fields: attr, stream, name, area, ext

field explanation type attr node stream number T_FX's stream id number name string file name ext string file extension area string file area

6.1.3.2 write nodes

Valid fields: attr, stream, data

 $\begin{array}{lll} \textbf{field} & \textbf{type} & \textbf{explanation} \\ \textbf{attr} & \textbf{node} \\ \textbf{stream} & \textbf{number} & \textbf{TEX's stream id number} \\ \textbf{data} & \textbf{table} & \textbf{a table representing the token list to be written} \\ \end{array}$

6.1.3.3 close nodes

Valid fields: attr, stream

field type explanation
attr node
stream number TFX's stream id number

6.1.3.4 special nodes

Valid fields: attr, data

field type explanation
attr node
data string The \special information

6.1.3.5 language nodes

Valid fields: attr, lang, left, right

```
field type explanation
attr node
lang number language id number
left number value of \lefthyphenmin
right number value of \righthyphenmin
```

6.1.3.6 local_par nodes

Valid fields: attr, pen_inter, pen_broken, dir, box_left, box_left_width, box_right, box_right_width

field	type	explanation
attr	node	
pen_inter	number	interline penalty
pen_broken	number	broken penalty
dir	number	the direction of this par
box_left	node	the \localleftbox
box_left_width	number	width of the $\label{localleftbox}$
box_right	node	the $\label{localrightbox}$
box_right_width	number	width of the \localrightbox

6.1.3.7 dir nodes

Valid fields: attr, dir, level, dvi_ptr, dvi_h

ileld	type	explanation
attr	node	
dir	number	the direction
level	number	nesting level of this direction whatsit
dvi_ptr	number	a saved dvi buffer byte offset
dir_h	number	a saved dvi position

6.1.3.8 pdf_literal nodes

Valid fields: attr, mode, data

ileTq	type	explanation
attr	node	
mode	number	The mode setting of this literal
data	string	The \pdfliteral information

6.1.3.9 pdf_refobj nodes

Valid fields: attr, objnum

field type explanation

attr node

objnum number the referenced PDF object number

6.1.3.10 pdf_refxform nodes

Valid fields: attr, width, height, depth, objnum

field type explanation
attr node
width number
height number
depth number
objnum number the referenced PDF object number

6.1.3.11 pdf_refximage nodes

Valid fields: attr, width, height, depth, objnum

field type explanation
attr node
width number
height number
depth number
objnum number the referenced PDF object number

6.1.3.12 pdf_annot nodes

Valid fields: attr, width, height, depth, objnum, data

field type explanation
attr node
width number
height number
depth number
objnum number the referenced PDF object number
data string the annotation data

6.1.3.13 pdf_start_link nodes

Valid fields: attr, width, height, depth, objnum, link_attr, action

field	type	explanation
attr	node	
width	number	
height	number	
depth	number	
objnum	number	the referenced PDF object number
link_attr	table	the link attribute token list
action	node	the action to perform

6.1.3.14 action items

Valid fields: action_type, named_id, action_id, file, new_window, data, ref_count These are a special kind of item that only appears inside pdf start link objects.

6.1.3.15 pdf_end_link nodes

Valid fields: attr

field type explanation
attr node

6.1.3.16 pdf_dest nodes

Valid fields: attr, width, height, depth, named_id, dest_id, dest_type, xyz_zoom, objnum

field	type	explanation
attr	node	
width	number	
height	number	
depth	number	
${\tt named_id}$	number	is the dest_id a string value?
dest_id	number or string	the destination id
dest_type	number	type of destination
xyz_zoom	number	
objnum	number	the PDF object number

6.1.3.17 pdf_thread nodes

Valid fields: attr, width, height, depth, named_id, thread_id, thread_attr

field type explanation attr node width number number height depth number named_id number is the tread_id a string value? number or string the thread id tread id thread_attr number extra thread information

6.1.3.18 pdf_start_thread nodes

Valid fields: attr, width, height, depth, named_id, thread_id, thread_attr

field type explanation attr node width number number height number depth named_id number is the tread_id a string value? tread id number or string the thread id extra thread information thread_attr number

6.1.3.19 pdf_end_thread nodes

Valid fields: attr

field type explanation

attr node

6.1.3.20 pdf_save_pos nodes

Valid fields: attr

field type explanation

attr node

6.1.3.21 pdf_snap_ref_point nodes

Valid fields: attr

field type explanation

attr node

6.1.3.22 pdf_snapy nodes

Valid fields: attr, final_skip, spec

field type explanation

attr node final_skip number

spec node pointer to a glue spec

6.1.3.23 pdf_snapy_comp nodes

Valid fields: attr, comp_ratio

field type explanation

attr node comp_ratio number

6.1.3.24 late_lua nodes

Valid fields: attr, reg, data

field type explanation

attr node

reg number LuA state id number data string data to execute

6.1.3.25 close_lua nodes

Valid fields: attr, reg

field type explanation

attr node

reg number LuA state id number

6.1.3.26 pdf_colorstack nodes

Valid fields: attr, stack, cmd, data

field type explanation

attr node

stack number colorstack id number
cmd number command to execute

data string data

6.1.3.27 pdf_setmatrix nodes

Valid fields: attr, data

field type explanation

attr node

data string data

6.1.3.28 pdf_save nodes

Valid fields: attr

field type explanation

attr node

6.1.3.29 pdf_restore nodes

Valid fields: attr

field type explanation

attr node

6.1.3.30 user_defined nodes

Valid fields: attr, user_id, type, value

field type explanation

attr node

user_id number id number

type number type of the value

value number

string node table

6.2 User-defined whatsits

7 Modifications

Besides the expected changes caused by new functionality, there are a number of not-so-expected changes. These are sometimes a side-effect of a new (conflicting) feature, or, more often than not, a change necessary to clean up the internal interfaces.

7.1 Changes from T_FX 3.141592

- There is no pool file, all strings are embedded during compilation.
- plus 1 filll1 does not generate an error. The extra l is simply typeset.
- The \endlinechar can be either added (values 0 or more), or not (negative values). If it is added, the character is always decimal 13 a/k/a ^M a/k/a carriage return (This change may be temporary).

7.2 Changes from ε -TEX 2.2

- The ε -TEX functionality is always present and enabled (but see below about TEXXET), so the prepended asterisk or -etex switch for INITEX is not needed.
- TEXXET is not present, so the primitives

```
\TeXXeTstate
\beginR
\beginL
\endR
\endL
are missing
```

7.3 Changes from PDFT_EX 1.40

• A number of utility functions is removed:

```
\pdfelapsedtime \pdffilesize \pdfstrcmp
\pdfescapehex \pdflastmatch \pdfunescapehex
\pdfescapename \pdfmatch
\pdfescapestring \pdfmdfivesum
\pdffiledump \pdfresettimer
\pdffilemoddate \pdfshellescape
```

• A few other experimental primitives are also provided without the extra pdf prefix, so they can also be called like this:

\primitive \ifabsnum \ifabsdim

- The definitions for new didot and new cicero are patched.
- The \pdfprimitive is bugfixed.
- The \pdftexversion is set to 200.

7.4 Changes from ALEPH RC4

• The input translations from ALEPH are not implemented, the related primitives are not available

\DefaultInputMode \noDefaultInputTranslation

\noDefaultInputMode \noInputTranslation \noInputTranslation

\InputMode \DefaultOutputTranslation \DefaultOutputTranslation \noDefaultOutputTranslation

\noDefaultOutputMode \noOutputTranslation \noOutputTranslation

\OutputMode

\DefaultInputTranslation

- A small series of bounds checking fixes to \ocp and \ocplist has been added to prevent the system from crashing due to array indexes running out of bounds.
- The \hoffset bug when \pagedir TRT is fixed, removing the need for an explicit fix to \hoffset
- A bug causing \fam to fail for family numbers above 15 is fixed.
- Some bits of ALEPH assumed 0 and null were identical. This resulted for instance in a bug that sometimes caused an eternal loop when trying to \show a box.
- A fair amount of minor bugs are fixed as well, most of these related to \tracingcommands output.
- The number of possible fonts, ocps and ocplists is smaller than their maximum ALEPH value (around 5000 fonts and 30000 ocps / ocplists).
- The internal function scan_dir() has been renamed to scan_direction() to prevent a naming clash.
- The ^^ notation can come in five and six item repetitions also, to insert characters that do not fit in the BMP.

7.5 Changes from standard WEB2C

- There is no mltex
- There is no enctex
- The following commandline switches are silently ignored, even in non-Lua mode:
 - -8hit
 - -translate-file=TCXNAME
 - -mltex

-enc

-etex

- \openout whatsits are not written to the log file.
- Some of the so-called web2c extensions are hard to set up in non-KPSE mode because texmf.cnf is not read: shell-escape is off (but that is not a problem because of LUA's os.execute), and the paranoia checks on openin and openout do not happen (however, it is easy for a LUA script to do this itself by overloading io.open).

8 Implementation notes

Primitives overlap 8.1

The primitives

\pdfpagewidth \pagewidth \pdfpageheight \pageheight \fontcharwd \charwd \fontcharht \charht \fontchardp \chardp \fontcharic \charic

are all aliases of each other.

8.2 Memory allocation

The single internal memory heap that traditional TFX used for tokens and nodes is split into two wholly separate arrays. Each of those can grow dynamically as needed.

The texmf.cnf settings related to main memory are no longer used (these are: main_memory, mem bot, extra mem top and extra mem bot). Out of main memory errors can still occur, but the limiting factor is now solely the amount of RAM in your system.

Also, the memory (de)allocation routines for nodes are completely rewritten. The relevant code now lives in the C file luanode.c, and now normally uses a dozen or so avail lists instead of a doublylinked model. At this moment, speed is still a little suboptimal because separate helper structures are maintained for debugging checks.

Because of the split in two arrays and the resulting differences in the data structures, some of the pascal web macros have been split. For instance, there are now vlink and vinfo as well as link and info. All access to the variable memory array is now hidden behind a macro called vmem.

The implementation of the growth of two arrays (via reallocation) introduces a potential pitfall: the memory arrays should never be used as the left hand side of a statement that can modify the array in question.

Sparse arrays

The \mathcode, \delcode, \catcode, \sfcode, \lccode and \uccode tables are now sparse arrays that are implemented in C. They are no longer part of the TFX equivalence table and because each had 1.1 million entries with a few memory words each, this makes a major difference in memory usage.

These assignments do not yet show up when using the etex tracing routines \tracingassigns and \tracingrestores (code simply not written yet)

A side-effect of the current implementation is that \global is now more expensive in terms of processing than non-global assignments.

See mathcodes.c and textcodes.c if you are interested in the gory details.

Also, the glyph ids within a font are now managed by means of a sparse array and glyph ids can go up to index $2^{21} - 1$.

8.4 Simple single-character csnames

Single-character commands are no longer treated aspecially in the internals, they are stored in the hash just like the multiletter csnames.

The code that displays control sequences explicitly checks if the length is one when it has to decide whether or not to add a trailing space.

8.5 Compressed format

The format is passed through zlib, allowing it to shrink to roughly half of the size it would have had in uncompressed form. This takes a bit more CPU cycles but much less disk I/O, so it should still be faster.

8.6 Binary file reading

All of the internal code is changed in such a way that if one of the read_xxx_file callbacks is not set, then the file is read by a C function using basically the same convention as the callback: a single read into a buffer big enough to hold the entire file contents. While this uses more memory than the previous code (that mostly used getc calls), it can be quite a bit faster (depending on your I/O subsystem).

9 Known bugs

The bugs below are going to be fixed eventually.

The top ones will be fixed soon, but in the later items either the actual problem is hard to find, or the code that causes the bug is going to be replaced by a new subsystem soon anyway.

- Not all of ALEPH's direction commands are handled properly in PDF mode yet: this affects all the top-bottom and bottom-top writing directions. And also, the \textdir command is broken.
- There is interference between rules and \pdfliteral. This is also likely related to the bidirectional algorithm.
- The TFM loader sometimes stores a full path instead of only a name, this prevents VF loading from working properly.
- The Lua setting of false_boundarychar=65536 gives an error.
- Letter spacing (\letterspacefont) is currently non-functional due to massive changes in the virtual font handling. This functionality may actually be removed completely in the future, because it is straightforward to set up letterspacing using the Lua 'define_font' interface.
- Attempting hyphenation in INITEX (sometimes) creates segfaults.
- Hyphenation can only deal with the Base Multilingual Plane (BMP)
- tex.print() and tex.sprint() do not work if \directlua is used in an oTP file (in the output of an expression rule).
- Handling of attributes in math mode is not complete. The data structures in math mode are quite different from those in text mode, so this will take some extra effort to implement correctly.
- When used inside \directlua, pdf.print() should create a literal node instead of flushin immedately.

10 TODO

On top of the normal extensions that are planned, there are some more specific small feature requests .

- Implement the TEX primitive \dimension, cf. \number
- Change the Lua table typetex.dimen to accept and return float values instead of strings
- Do something about \withoutpt and/or a new register type \real?
- Create callback for the automatic creation of missing characters in fonts
- Implement the TFX primitive \htdp?
- Do boxes with dual baselines.
- A way to (re?)calculate the width of a \vbox, taking only the natural width of the included items into account.
- Make the number of the output box configurable.
- Switch to FontForge 2.0
- Complete the attributes in math and switch the nodes to a double-linked list.
- Move the raw bytes outside of the legal UNICODE range, to prevent collisions.
- Implement csname lookups for tex.box access.
- Integrate the various PDFTEX extended font codes for hz en protruding into the font table
