Introduction 1

This book will eventually become the reference manual of LUATEX. At the moment, it simply reports the behavior of the executable matching the snapshot date in the title page.

Features may come and go. The current version of LUATEX is not meant for production and users cannot depend on functionality staying the same.

Nothing in the API is considered stable just yet. This manual therefore simply reflects the current state of the executable. Absolutely nothing on the following pages is set in stone. When the need arises, anything can (and will) be changed without prior notice.

If you are unhappy with this situation, wait for the public beta's.

LUATEX consists of a number of interrelated but (still) distinguishable parts:

- PDFTFX version 1.40 (currently in beta)
- ALEPH RC4 (from the TEXLIVE repository)
- Functionality of ε -TFX 2.2
- Lua 5.1
- Dedicated lua libraries
- Various TFX extensions
- Compiled source code to glue it all together

LUATEX has two separate identities:

- 1. When \pdfoutput10 is set to one, LUATEX behaves like PDFTEX, with the addition of (8-bit) OTP processing. In this mode, fonts are limited to 256 characters, and hyphenation is only available for 8-bit font encodings. Attempts to use the Aleph direction commands will generate erroneous output.
- 2. When \pdfoutput10 is zero, LUATEX behaves like ALEPH with the addition of the microtypography features. In this mode, fonts can have 65536 characters, and the whole Unicode base plane can be hyphenated (assuming a proper font encoding). The PDFTFX commands that are not specific to the PDF output format should work.

In either mode, I/O translation processes, tcx files, enctex, cannot be used. The encoding items are superseded by a Lua-based solution (reader6 callbacks).

Basic TFX enhancements

2.1 Unicode support

Text input and output is now considered to be Unicode text, so characters can use the full range of Unicode $(2^{20} + 2^{16} = 10^{10})$ = 114111).

For now, it only makes sense to use values above the base plane ("FFFF) for \mathcode9 and \catcode8 assignments, since the fonts as well as the hyphenation patterns are still limited to at the most 16-bit values, so the other command will not know what to do with those high values.

Many primitives are affected by this. For instance, \char5 now accepts values between 0 and 1114111. This should not be a problem for well-behaved input files, but it could create incompatibilities for input that would have generated an error when processed by older TEX-based engines.

Primitive	Bits	Hex	Range
\char5	21	"10FFFF	$(2^{20} + 2^{16})$
\chardef8	21 = 21	"10FFFF="10FFFF	$(2^{20} + 2^{16}) = (2^{20} + 2^{16})$
\lccode7	21 = 21	"10FFFF="10FFFF	$(2^{20} + 2^{16}) = (2^{20} + 2^{16})$
\uccode7	21 = 21	"10FFFF="10FFFF	$(2^{20} + 2^{16}) = (2^{20} + 2^{16})$
\sfcode7	21 = 15	"10FFFF="7FFF	$(2^{20} + 2^{16}) = (2^{15})$
\catcode8	21 = 4	"10FFFF="F	$(2^{20} + 2^{16}) = (2^4)$
\mathchardef12	21 = 15	"10FFFF="8000	$(2^{20} + 2^{16}) = (2^3 * 2^8 * 2^4)$
\mathcode9	21 = 15	"10FFFF="8000	$(2^{20} + 2^{16}) = (2^3 * 2^8 * 2^4)$
\delcode8	21 = 27	"10FFFF="7FFFFF	$(2^{20} + 2^{16}) = (2^3 * 2^4 * 2^8 * 2^4 * 2^8)$

As far as the core engine is aware, all input and output to text files is UTF-8 encoded. Input files can be preprocessed using the reader6 callback. This will be explained in a later chapter.

Output to the terminal uses ^2 notation for the lower control range, with the exception of ^13, ^^J3 and ^^M3. These are considered 'safe' and therefore printed as-is.

No normalization of the Unicode input takes place yet, but that will happen eventually.

2.2 Wide math characters

Text is now extended up to the full Unicode range, but math mode deals mostly with glyphs in fonts directly, and fonts tend to be 16-bit at maximum.

Therefore, the math primitives from ALEPH are kept mostly as-is, except for the ones that convert from input to math commands. The extended commands (with the 'o1' prefix) accept 16-bit glyph indices in one of 256 possible families. The traditional TFX primitives are unchanged, their arguments are upscaled internally.

Primitive	Bits	Hex	Range
\mathchar9	15	"7FFF	$(2^3 * 2^8 * 2^4)$
\delimiter10	27	"7FFFFFF	$(2^3 * 2^4 * 2^8 * 2^4 * 2^8)$
\omathchar10	27	"7FFFFFF	$(2^3 * 2^{16} * 2^8)$
\odelimiter11	27 + 24	"7FFFFFF+"FFFFFF	$(2^3 * 2^8 * 2^{16}) + (2^8 * 2^{16})$
\omathchardef13	21=27	"10FFFF="8000000	$(2^{20} + 2^{16}) = (2^3 * 2^{16} * 2^8)$
\omathcode10	21=27	"10FFFF="8000000	$(2^{20} + 2^{16}) = (2^3 * 2^{16} * 2^8)$
\odelcode9	21 = 27 + 24	"10FFFF="7FFFFFF+	$(2^{20} + 2^{16}) = (2^3 * 2^8 * 2^{16}) +$
		"FFFFF	$(2^8 * 2^{16})$

2.3 Extended register tables

All registers can be <16-bit number>15, as in ALEPH. The affected commands are:

\count6	\unhbox7
\dimen6	\unvbox7
\skip5	\сору5
\muskip7	\unhcopy8
\marks6	\unvcopy8
\toks5	\wd3
\countdef9	\ht3
\dimendef9	\dp3
\skipdef8	\setbox7
\muskipdef10	\vsplit7
\toksdef8	
\box4	

2.4 Lua related primitives

In order to merge lua code with TEX input, a few new primitives are needed. LUATEX has support for 65536 separate lua interpreter states. States are automatically created based on the integer argument to the primitives \directlua and \latelua.

2.4.1 \directlua

The primitive \directlua is used to execute lua code. The syntax is

```
\directlua \langle 16-bit number \rangle \langle general text \rangle
```

The $\langle \text{general text} \rangle$ is fed into the lua interpreter state indicated by the $\langle 16\text{-bit number} \rangle$. If the state does not exist yet, then it will be initialized automatically.

This command is expandable.

2.4.2 \latelua

\latelua stores lua code in a whatsit that will be processed inside the output routine. It is very similar to \pdfliteral11.

Any output it produces should go straight to the PDF file, but at the moment it is broken (there is no way to generate the desired output)

\latelua ["direct"|"page"] \langle 16-bit number \rangle \text \rangle

2.4.3 \luaescapestring

This primitive converts a TFX token string so that it can be safely used as the contents of a LUA string: embedded backslashes, double quotes and single quotes are escaped by prepending an extra token consisting of a backslash with catcode 12.

\luaescapestring \langle general text \rangle

2.4.4 \luaclose

This primitive allows you to close a lua state, freeing all of its used memory.

\luaclose \langle 16-bit number \rangle

You cannot close lua state zero (0), any attempt to do so will be silently ignored.

States are only closed automatically when a fatal (out of memory) error occurs, but at that point LUATEX will exit anyway.

2.5 New ε -TFX primitives

2.5.1 \clearmarks

This primitive clears a marks class completely, resetting all three connected mark texts to empty.

\clearmarks \langle 16-bit number \rangle

2.5.2 \formatname

\formatname's syntax is identical to \jobname8.

In initex, the expansion is empty. Otherwise, the expansion is the value that \jobname8 had during the initex run that dumped the currently loaded format.

2.5.3 \scantextokens

The syntax of \scantextokens is identical to \scantokens11.

This is a slightly adapted version of ε -TFX's \scantokens11. The differences are:

- The last (and usually only) line does not have a \endlinechar12 appended
- \scantextokens14 never raises an EOF error, and it does not execute \everyeof9 tokens.
- The 'while end of file' tests are not executed, allowing the expansion to end on a different grouping level or while a conditional is still incomplete

2.5.4 Catcode tables

Catcode tables are a new feature that allows you to switch to a predefined catcode regime in a single statement. You can have a practically unlimited number of different tables (at this moment up to 268,435,456. The limit depends on an array allocation).

The subsystem is backward compatible: if you never use the following commands, your document will not notice any difference in behavior compared to traditional TFX.

The contents of each catcode table is independent of any other catcode tables, and their contents is stored and retrieved from the format file.

2.5.4.1 \catcodetable

\catcodetable \(28\)-bit number \(\)

The \catcodetable switches to a different catcode table. Such a table has to be previously created using one of the two primitives below, or it has to be zero (table zero is initialized by initex)

2.5.4.2 \initcatcodetable

\initcatcodetable \(28\)-bit number \(\)

The \initcatcodetable creates a new table with catcodes identical to those defined by initex:

^^M3 (<return>)</return>	car ret7	5
1 (space)	spacer6	10
, , ,	•	10
\\2	escape6	0
%1	comment7	14
^^?3 (<delete>)</delete>	invalid_char12	15
^^@3 (<null>)</null>	ignore6	9
a1-z1	letter6	11
A1-Z1	letter6	11
everything else	other5	12

The new catcode table is allocated globally: it will not go away after the current group has ended. If the supplied number is the currently active table, an error is raised.

2.5.4.3 \savecatcodetable

\savecatcodetable \(28\)-bit number \(\)

\savecatcodetable copies the current set of catcodes to a new table with the requested number. The definitions in this new table are all treated as if they were made in the outermost level.

The new table is allocated globally: it will not go away after the current group has ended. If the supplied number is the currently active table, an error is raised.

3 Lua general

3.1 Initialization

Whenever the LUATEX executable starts, it looks for a --lua5 command—line option. If such an option is present, it will enter an alternative mode of command—line parsing.

In this mode, it will only interpret a very small subset of the command—line directly:

```
-lua=s load and execute a lua init script-help display help and exit-version display version and exit
```

If the Lua script can not be found using the actual name of the command—line, a second attempt is made by prepending the value of the environment variable LUATEXDIR9, if it esists.

Then the script is loaded and executed. It will find the entire commandline in the table arg3, beginning with arg[0]6, that is the name of the executable. At the end of script execution, LUATEX will fetch some of the processed command line options from the texconfig9 table (see the description of the texconfig9 table later on in this document).

This happens very early on. So early, in fact, that none of TEX's initializations have taken place yet. For that reason, the tex3 and pdf3 tables are off-limits during the execution of the startup file (they are nilled). Special care is taken that texio.write11 and texio.write_nl14 function properly, so that you can at least report your actions to the log file when it eventually becomes opened (note that TEX does not even know it's \jobname8 yet at this point).

The file is loaded into Lua state 0, and everything you do will remain visible during the rest of the run, with the exception of the tex3 and pdf3 tables: those will be restored to their normal meaning right after the execution of the script.

We recommend you use the startup file only for your own TEX-independent initializations (if you need any), to parse the command—line, set values in the texconfig9 table, and register the callbacks you need.

Unless the texconfig9 table tells it not to start kpathsea at all (set texconfig.kpse_init19 to false5 for that), it also acts on three other command—line options:

```
-fmt=s set the format name
-progname=s set the progname (only for kpathsea)
-ini enable initex mode
```

In order to initialize the built-in kpathsea library properly, LUATEX needs to know the correct 'progname' to use, and for that it needs to check -progname9 and -ini4 and -fmt4 (if -progname9 is missing).

3.2 Lua changes

Two modules that are normally external are statically linked in with LUATEX: slnunicode10 and luazip6.

The read("*line")13 function from the io library has been adjusted so that it is line-ending neutral: any of LF2, CR2 or typeCR+LF are accepted.

The tostring()10 printer for numbers has been changed so that it returns '0' instead of something like '2e-5' (which confused TEX enormously).

4 Lua Libraries

The interfacing between TFX and LuA is facilitated by a set of LuA modules.

4.1 The tex library

The tex table contains a large list of virtual internal TFX parameters that are partially writable.

The designation 'virtual' means that these items are not properly defined in Lua, but are only frontends that are handled by a metatable that operates on the actual TEX values. As a result, most of the lua table operators (like pairs5 and #1) do not work on such items.

At the moment, it is possible to access almost every parameter that has these characteristics:

- You can use it after \the4
- It is a single token.

This excludes parameters that need extra arguments, like \the\scriptfont15.

The subset comprising simple integer and dimension registers are writable as well as readable (stuff like \tracingcommands16 and \parindent10).

4.1.1 Integer parameters

The integer parameters accept and return lua numbers.

Read-write:

tex.adjdemerits15	tex.globaldefs14
tex.binoppenalty16	tex.hangafter13
tex.brokenpenalty17	tex.hbadness12

Read-only:

tex.deadcycles14 tex.prevgraf12 tex.insertpenalties19 tex.spacefactor15 tex.parshape12

4.1.2 Dimension parameters

The dimension parameters accept lua numbers (signifying scaled points) or strings (with included dimension). The result is always a string.

Read-write:

tex.boxmaxdepth15 tex.pdfdestmargin17 tex.delimitershortfall22 tex.pdfeachlinedepth20 tex.displayindent17 tex.pdfeachlineheight21 tex.pdffirstlineheight22 tex.displaywidth16 tex.pdfhorigin14 tex.emergencystretch20 tex.pdflastlinedepth20 tex.hangindent14 tex.hfuzz9 tex.pdflinkmargin17 tex.hoffset11 tex.pdfpageheight17 tex.hsize9 tex.pdfpagewidth16 tex.lineskiplimit17 tex.pdfpxdimen14 tex.mathsurround16 tex.pdfthreadmargin19 tex.pdfvorigin14 tex.maxdepth12 tex.predisplaysize18 tex.nulldelimiterspace22 tex.scriptspace15 tex.overfullrule16 tex.pagebottomoffset20 tex.splitmaxdepth17 tex.pageheight14 tex.vfuzz9 tex.pagerightoffset19 tex.voffset11 tex.vsize9 tex.pagewidth13 tex.parindent13 Read-only: tex.pagedepth13 tex.pageshrink14 tex.pagefilllstretch20 tex.pagestretch15 tex.pagefillstretch19 tex.pagetotal13 tex.pagefilstretch18 tex.prevdepth13 tex.pagegoal12

4.1.3 Direction parameters

All direction parameters are read-only and return a lua string

tex.bodydir11 tex.pardir10 tex.mathdir11 tex.textdir11 tex.pagedir11

4.1.4 Glue parameters

All glue parameters are read-only and return a lua string

```
tex.abovedisplayshortskip25 tex.parskip11
tex.abovedisplayskip20 tex.rightskip13
tex.baselineskip16 tex.spaceskip13
tex.belowdisplayshortskip25 tex.splittopskip16
tex.belowdisplayskip20 tex.tabskip11
tex.leftskip12 tex.topskip11
tex.lineskip12 tex.xspaceskip14
tex.parfillskip15
```

4.1.5 Muglue parameters

All muglue parameters are read-only and return a lua string

```
tex.medmuskip13
tex.thickmuskip15
tex.thinmuskip14
```

4.1.6 Tokenlist parameters

All tokenlist parameters are read-only and return a lua string

```
tex.errhelp11 tex.everyvbox13
tex.everycr11 tex.output10
tex.everydisplay16 tex.pdfpageattr15
tex.everyeof12 tex.pdfpageresources20
tex.everyhbox13 tex.pdfpagesattr16
tex.everyjob12 tex.pdfpkmode13
tex.everymath13
tex.everypar12
```

4.1.7 Convert commands

The supported commands at this moment are:

```
tex.AlephVersion16 tex.formatname14
tex.Alephrevision17 tex.jobname11
tex.OmegaVersion16 tex.pdfnormaldeviate20
tex.Omegarevision17 tex.pdftexbanner16
tex.eTeXVersion15 tex.pdftexrevision18
tex.eTeXrevision16
```

All 'convert' commands are read-only and return a lua string

This list looks haphazard, but it really is not. These are all the cases of the 'convert' internal command that do not require an argument.

4.1.8 Count, dimension and token registers

TEX's counters (\count6), dimensions (\dimen6) and token (\toks5) registers can be accessed and written to using three virtual sub-tables of the tex3 table:

```
tex.count13
tex.dimen13
tex.toks12
```

It is possible to use the names of relevant \countdef9, \dimendef9, or \toksdef8 control sequences as indices to these tables:

```
tex.count.scratchcounter = 032
enormous = tex.dimen["maxdimen"]36
```

In this case, luatex looks up the value for you on the fly. You have to use a valid \countdef9 (or \dimendef9, or \toksdef8), anything else will generate an error (the goal is to eventually also allow <chardef tokens>16 and even macros that expand into a number)

The count registers accept and return lua numbers.

The dimension registers accept lua numbers (in scaled points) or strings (with included dimension). The result is always a number in scaled points.

The token registers accept and return lua strings. Lua strings are converted to token lists using \the\toks9 style expansion.

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setdimen(number n, string s)34
tex.setdimen(string s, string s)34
tex.setdimen(number n, number n)34
tex.setdimen(string s, number n)34
number n = tex.getdimen(number n)35
number n = tex.getdimen(string s)35

tex.setcount(number n, number n)34
tex.setcount(string s, number n)34
number n = tex.getcount(number n)35
number n = tex.getcount(string s)35

tex.settoks (number n, string s)35

tex.settoks (string s, string s)34
string s = tex.gettoks (number n)35
string s = tex.gettoks (string s)35
```

4.1.9 Box register size information

The current dimensions of $\box4$ registers can be read and altered using three other virtual subtables:

```
tex.wd10
tex.ht10
tex.dp10
```

These are indexed strictly by number.

The box size registers accept lua numbers (in scaled points) or strings (with included dimension). The result is always a number in scaled points.

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setboxwd(number n, string s)34
tex.setboxwd(number n, number n)34
number n = tex.getboxwd(number n)35
tex.setboxht(number n, string s)34
tex.setboxht(number n, number n)34
number n = tex.getboxht(number n)35
tex.setboxdp(number n, string s)34
tex.setboxdp(number n, number n)34
number n = tex.getboxdp(number n)35
```

4.1.10 Print functions

The tex3 table also contains the three print functions that are the major interface from lua scripting to T_EX .

The arguments to these three functions are all stored in an in-memory virtual file that is fed to the TEX scanner as the result of the expansion of \directlua10.

The total amount of returnable text from a \directlua10 command is only limited by available system RAM. However, each separate printed string has to fit completely in TeX's input buffer.

4.1.10.1 tex.print9

```
tex.print(<string s>, ...)29
tex.print(<number n>, <string s>, ...)41
```

Each string argument is treated by TFX as a separate input line.

The optional parameter can be used to print the strings using the catcode regime defined by catcodetable13 n. If n is not a valid catcode table, then it is ignored, and the currently active catcode regime is used instead.

The very last string of the very last tex.print()11 command in a \directlua10 will not have the \endlinechar12 appended, all others do.

4.1.10.2 tex.sprint10

```
tex.sprint(<string s>, ...)30
tex.sprint(<number n>, <string s>, ...)42
```

Each string argument is treated by TFX as a special kind of input line that makes it suitable for use as a partial line input mechanism:

- TFX does not switch to the 'new line' state, so that leading spaces are not ignored
- no \endlinechar12 is inserted
- trailing spaces are not removed

4.1.10.3 tex.write9

```
tex.write(<string s>, ...)29
```

Each string argument is treated by TFX as a special kind of input line that makes is suitable for use as a quick way to dump information:

- all catcodes on that line are either 'space' (for " ") or 'character' (for all others).
- there is no \endlinechar12 appended.

4.2 The texio library

This library takes care of the low-level I/O interface.

4.2.1 Printing functions

4.2.1.1 texio.write11

```
texio.write(string target, tring s)37
texio.write(string s)23
```

Without the target6 argument, Writes the string to the same location(s) TFX writes messages to at this moment. If \batchmode10 is in effect, it writes only to the log, otherwise it writes to the log and the terminal.

The optional target6 can be one of three possibilities: 'term', 'log' or 'term and log'.

4.2.1.2 tex.write nl12

```
texio.write_nl(string target, tring s)40
texio.write_nl(string s)26
```

Like texio.write11, but make sure that the string s will appear at the beginning of a line. You can use an empty string if you only want to move to the next line.

4.3 The pdf library

This table contains the current h1 en v1 values that define the location on the output page. The values can be queried and set using scaled points as units.

```
pdf.v9
pdf.h9
```

The associated function calls are

```
pdf.setv(number n)23
number n = pdf.getv()26
pdf.seth(number n)23
number n = pdf.geth()26
```

4.4 The callback library

This library has a function that is used to register callbacks, and a function that lists the registered callbacks

The callback library is only available in lua state zero (0).

```
callback.register(string <callback name>,function <callback_func>)69
callback.register(string <callback name>,nil)48
```

where the (callback name) is a predefined callback name, see below.

LUATEX internalizes the callback function in such a way that it does not matter if you redefine a function accidentally.

Callback assignments are always global. You can use the special value 'nil' instead of a function for clearing the callback.

```
table <info> = callback.list()33
```

The keys in the table are the known callback names, the value is a boolean where true4 means that the callback is currently set (active).

4.4.1 File discovery callbacks

4.4.1.1 find read file14 and find write file15

You callback function should have the following conventions:

```
string <actual_name> = function (number <id_number>, string <asked_name>)76
```

Arguments:

id_number

zero for the log or \input6 files, or TeX's \read5 or \write6 number incremented by one (\read50 becomes 1).

asked_name

the user—supplied filename, as found by \input6, or \openin7, or \openout8.

Return value:

actual_name

the filename used. For the very first file that is read in by TEX, you have to make sure you return an actual_name11 that has an extension and that is suitable for use as jobname7. If you don't, you will have to manually fix the name for the log file and output file, and an eventual format filename will become mangled, since these depend on the jobname.

4.4.1.2 find_font_file14

You callback function should have the following conventions:

```
string <actual_name> = function (string <asked_name>)56
```

The asked_name10 is an OTF or TFM font metrics file.

4.4.1.3 find output file16

You callback function should have the following conventions:

```
string <actual_name> = function (string <asked_name>)56
```

The asked_name10 is the PDF or DVI file for writing.

4.4.1.4 find format file16

You callback function should have the following conventions:

```
string <actual name> = function (string <asked name>)56
```

The asked_name10 is a format file for reading (the format file for writing is always opened in the current directory).

4.4.1.5 find_truetype_file18 and find_type1_file15

You callback function should have the following conventions:

```
string <actual_name> = function (string <asked_name>)56
```

The asked_name10 is a font file. This callback is called while LUATEX is building its internal list of needed font files, so the actual timing may surprise you. Your return value is later fed back into the matching read_file10 callback.

Strangely enough, find_type1_file15 is also used for OpenType (off) fonts.

4.4.1.6 find_image_file15

You callback function should have the following conventions:

```
string <actual_name> = function (string <asked_name>)56
```

The asked_name10 is an image file. Your return value is used to open a file from the harddisk, so make sure you return something that is considered the name of a valid file by your operating system.

4.4.2 File reading callbacks

4.4.2.1 open_read_file14

You callback function should have the following conventions:

```
table <env> = function (string <file_name>)46
```

Argument:

file_name

the filename returned by a previous find_read_file14 or the return value of kpse_find_file()16 if there was no such callback defined.

Return value:

env

this is a table containing one required and one optional callback functions for this file. The required field is 'reader6' and the associated function will be called once for each new line to be read, the optional one is 'close5' that will be called once when LUATEX is done with the file. Neither function will receive an argument, so you should set you a proper closure for them.

4.4.2.1.1 reader6

LUATFX will run this function whenever it needs a new input line from the file.

```
function ()13
 return string <line>24
end5
```

Your function should return either a string or 'nil'. The value 'nil' signals that the end of file has occurred, and will make TEX call the optional 'close5' function next.

4.4.2.1.2 close5

LUATEX will optionally run this function when it needs to close the file.

```
function ()13
  return10
end5
```

Your function should not return any value.

4.4.2.2 read font file14

This function is called when TEX needs to read a ofm3 or tfm3 file.

```
function (string <name>)29
        return boolean <success>, string <data>, number <data_size>67
     end8
success
```

return false when the file cannot be found.

the bytes comprising the file.

data_size

the length of the data4, in bytes.

return an empty string and zero if the file was found but there was a reading problem.

4.4.2.3 read vf file12

Like read_font_file14, but for virtual fonts.

4.4.2.4 read_ocp_file13

Like read font file14, but for ocp files.

4.4.2.5 read_map_file13

Like read_font_file14, but for map files.

4.4.2.6 read_enc_file13

Like read_font_file14, but for enc files.

4.4.2.7 read_sfd_file13

Like read_font_file14, but for subfont definition files.

4.4.2.8 read_miscfonts_file19

Like read_font_file14, but for t3 font (pgc) files.

4.4.2.9 read_pk_file12

Like read_font_file14, but for pk bitmap files. The argument <name>6 is a bit special in this case. It's form is

<base res>dpi/<fontname>.<actual res>pk41

So you may be asked for 600dpi/manfnt.720pk19. It is up to you to find a 'reasonable' bitmap file to go with that specification.

4.4.2.10 read_data_file14

Like read_font_file14, but for embedded files (\pdfobj file "..."18).

4.4.2.11 read_truetype_file18

Like read_font_file14, but for truetype font files. The name4 is a path name as returned by find_truetype_file18 or kpse_find_file14.

4.4.2.12 read_type1_file15

Like read_font_file14, but for type1 font files. The name4 is a path name as returned by find_type1_file15 or kpse_find_file14.

4.4.2.13 read_opentype_file18

Like read_font_file14, but for opentype font files. The name4 is a path name as returned by find_type1_file15 or kpse_find_file14.

4.4.3 Information reporting callbacks

4.4.3.1 start run9

```
function ()13
```

Replaces the code that prints LUATFX's banner

4.4.3.2 stop_run8

```
function ()13
```

Replaces the code that prints LUATEX's statistics and 'Output written to' messages.

4.4.3.3 start_page_number17

```
function ()13
```

Replaces the code that prints the [1 and the page number at the begin of \shipout8. This callback will also override the printing of box information that normally takes place when \tracingoutput14 is positive.

4.4.3.4 stop_page_number16

```
function ()13
```

Replaces the code that prints the]1 at the end of \shipout8

4.4.3.5 show_error_hook15

```
function (string <message>, string <indicator>, number <lineno>)69 return end function (string <message>, number <indicator>, number70 <lineno>) return end25
```

This callback is run from inside the TEX error function, and the idea is to allow you to do some extra reporting on top of what TEX already does (none of the normal actions are removed).

message

is the formal error message $T_E X$ has given to the user (the line after the "!") indicator

is either a filename (when it is a string) or a location indicator (a number) that can means lots of different things like a token list id or a \read5 number.

lineno

is the current line number

This is an investigative item only, only for 'testing the water'.

The final goal is the total replacement of T_EX's error handling routines, but that needs lots of adjustments in the web source because T_EX deals with errors in a somewhat haphazard fashion.

4.5 The lua library

This library contains two read-only items:

4.5.1 Variables

```
number n = lua.id22
```

the id number of the instance

```
string s = lua.version27
```

a luatex version identifier string (currently "0.1"5)

4.5.2 Lua bytecode registers

Lua registers can be used to communicate lua functions across lua states. The accepted values for assignments are functions and nil. Likewise, the retrieved value is either a function or nil.

```
lua.bytecode[n] = function () .. end41
lua.bytecode[n]()22
```

The contents of the lua.bytecode12 array is stored inside the format file as actual lua bytecode, so it can also be used to preload lua code.

The associated function calls are

```
function f = lua.getbytecode(number n)43
lua.setbytecode(number n, function f)42
```

4.6 The kpse library

4.6.1 kpse.find_file14

The most important function in the library is find_file:

```
string f = kpse.find file(string filename)43
 string f = kpse.find_file(string filename, string ftype)57
 string f = kpse.find_file(string filename, boolean mustexist)62
 string f = kpse.find_file(string filename, string ftype, boolean mustexist)76
Arguments:
filename
  the name of the file you want to find, with or without extension.
  maps to the '-format' argument of kpsewhich9. The supported values are:
   "gf"4
                                            "TeX system documentation"26
   "pk"4
                                            "texpool"9
   "bitmap font"13
                                            "TeX system sources"20
   "tfm"5
                                            "PostScript header"19
  "afm"5
                                            "Troff fonts"13
   "base"6
                                            "type1 fonts"13
  "bib"5
                                            "vf"4
  "bst"5
                                            "dvips config"14
  "cnf"5
                                            "ist"5
   "ls-R"6
                                            "truetype fonts"16
  "fmt"5
                                            "type42 fonts"14
                                            "web2c files"13
   "map"5
  "mem"5
                                            "other text files"18
   "mf"4
                                            "other binary files"20
   "mfpool"8
                                            "misc fonts"12
   "mft"5
                                            "web"5
                                            "cweb"6
   ''mp''4
                                            "enc files"11
   "mppool"8
   "MetaPost support"18
                                            "cmap files"12
   "ocp"5
                                            "subfont definition files"26
   "ofm"5
                                            "opentype fonts"16
  "op1"5
                                            "pdftex config"15
   "otp"5
                                            "lig files"11
   "ovf"5
                                            "texmfscripts"14
   "ovp"5
   "graphic/figure"16
   "tex"5
```

```
The default type is "tex"5. mustexist
```

is similar to kpsewhich's '-must-exist', and the default is 'false'. If you specify 'true' (or a non-zero integer), then the kpse library will search the disk as well as the ls-R databases.

4.6.2 kpse.expand_path16

Like kpsewhich's '-expand-path':

```
string r = kpse.expand_path(string s)42
```

4.6.3 kpse.expand_var15

Like kpsewhich's '-expand-var':

```
string r = kpse.expand_var(string s)41
```

4.6.4 kpse.expand_braces18

Like kpsewhich's '-expand-braces':

```
string r = kpse.expand_braces(string s)44
```

4.7 The statistics library

This contains a number of run—time configuration items that you may find useful in message reporting, as well as an iterator function that gets all of the names and values as a table.

```
table <info> = statistics.list()35
```

The keys in the table are the known items, the value is the current value.

Almost all of the values in statistics10 are fetched through a metatable at run—time whenever they are accessed, so you cannot use pairs5 onstatistics10, but you *can* use pairs5 on <info>6, of course.

If you do not need the full list, you can also ask for a single item by using it's name as an index into statistics 10.

The current list is:

Key Explanation pdf_gone written pdf bytes

pdf_ptr not yet written pdf bytes

dvi_qone written dvi bytes

dvi_ptr not yet written dvi bytes

total_pages number of written pages output_file_name name of the pdf or dvi file log_name name of the log file banner terminal display banner

4.8 The texconfig table

This is a table that is created empty. A startup lua script could fill this table with a number of settings that are read out by the executable after loading and executing the startup file.

5 Modifications

Besides the expected changes caused by new functionality, there are a number of not-so-expected changes. These are sometimes a side-effect of a new (conflicting) feature, or, more often than not, a change necessary to clean up the internal interfaces.

5.1 Changes from T_EX 3.141592

- There is no pool file, all strings are embedded during compilation.
- "plus 1 fillll" does not generate an error. The extra 'l' is simply typeset.

5.2 Changes from ε -TEX 2.2

- The ε -T_EX functionality is always present and enabled (but see below about T_EXX_ET), so the prepended asterisk or -etex5 switch for initex is not needed.
- TFXXET is not present, so the primitives

```
\TeXXeTstate16
\beginR11
\beginL11
\endR9
\endL9
```

are missing

5.3 Changes from PDFT_EX 1.40

• A number of 'utility functions' is removed:

```
\pdfelapsedtime19
\pdfescapehex17
\pdfescapename18
\pdfescapestring20
\pdffiledump16
\pdffilemoddate19
\pdffilesize16
\pdflastmatch17
\pdfmatch13
\pdfmdfivesum17
\pdfresettimer18
\pdfshellescape19
```

```
\pdfstrcmp14
\pdfunescapehex19
```

• A few other experimental primitives are provided without the extra 'pdf' prefix, so they are simply called:

```
\primitive14
\ifprimitive16
\ifabsnum13
\ifabsdim13
```

5.4 Changes from ALEPH RC4

• The input translations from ALEPH are not implemented, the related primitives are not available

```
\DefaultInputMode21
\noDefaultInputMode23
\noInputMode16
\InputMode14
\DefaultOutputMode22
\noDefaultOutputMode24
\noOutputMode17
\OutputMode15
\DefaultInputTranslation28
\noDefaultInputTranslation30
\noInputTranslation23
\InputTranslation21
\DefaultOutputTranslation29
\noDefaultOutputTranslation31
\noOutputTranslation24
\OutputTranslation22
```

- A small series of bounds checking fixes to \ocp4 and \ocplist8 has been added to prevent the system from crashing due to array indexes running out of bounds.
- The \hoffset8 bug when \pagedir TRT12 is fixed, removing the need for an explicit fix to \hoffset8
- A bug causing \fam4 to fail for family numbers above 15 is fixed.
- Some bits of ALEPH assumed 01 and null4 were identical. This resulted for instance in a bug that sometimes caused an eternal loop when trying to \show5 a box.
- A fair amount of minor bugs are fixed as well, most of these related to \tracingcommands16 output.
- The number of fonts, ocps and ocplists is capped off at about 8% of their maximum ALEPH value (around 5000 for each).

5.5 Changes from standard WEB2C

- There is no mltex
- There is no enctex
- The following command-line switches are silently ignored:

```
-8bit7
-translate-file=TCXNAME25
-mltex8
-enc6
-etex7
```

- \openout8 whatsits are not written to the log file.
- Some of the so-called web2c extensions are hard to set up in non-kpse mode because texmf.cnf is not read: shell-escape12 is off (but that is not a problem because of Lua's os.execute10), and the paranoia checks on openin6 and openout7 do not happen (however, it is easy for a Lua script to do this itself by overloading io.open7).

6 Implementation notes

1 Primitives overlap

The primitives

```
\pdfpagewidth and \pagewidth,35
\pdfpageheight and \pageheight,37
\fontcharwd and \charwd,30
\fontcharht and \charht,30
\fontchardp and \chardp,30
\fontcharic and \charic,30
```

are all aliases of each other.

2 Sparse arrays

The \mathcode9, \delcode8, \catcode8, \sfcode7, \lccode7 and \uccode7 tables are now sparse arrays that are implemented in C. They are no longer part of the TEX "equivalence table" and because each had 1.1 million entries with a few memory words each, this makes a major difference in memory usage.

These assignments do not yet show up when using the etex tracing routines \tracingassigns15 and \tracingrestores16 (code simply not written yet)

A side-effect of the current implementation is that \global7 is now more expensive in terms of processing than non-global assignments.

See mathcodes.c11 and textcodes.c11 if you are interested in the gory details.

3 Simple single-character csnames

Single-character commands are no longer treated special in the internals, they are stored in the hash just like the multiletter csnames.

The code that displays control sequences explicitly checks if the length is one when it has to decide whether or not to add a trailing space.

4 Compressed format

The format is passed through zlib, allowing it to shrink to roughly a third of the size it would have had in uncompressed form. This takes a bit more CPU cycles but much less disk I/O, so it should still be faster.

The chosen compression factor is fairly low, equivalent to gzip -37.

5 Binary file reading

All of the internal code is changed in such a way that if one of the read_xxx_file13 callbacks is not set, then the file is read by a C function using basically the same convention as the callback: a single read into a buffer big enough to hold the entire file contents. While this uses more memory than the previous code (that mostly used getc4 calls), it can be quite a bit faster (depending on your I/O subsystem).

7 Known bugs

- Under some conditions, the **autoexpand** font feature can crash the executable.
- Hyphenation can only deal with the Base Multilingual Plane (BMP)
- There are (sometimes?) UTF-8 encoded UTF-8 bytes in the pseudo-buffer lines that are shown during error()

8 TODO

On top of the 'normal' extensions that are planned, there are some more specific small feature requests

- Low-level support is still missing but needed to escape from the UTF-8 regime when dealing with \special8 and \pdfliteral11.
- Implement the T_EX primitive \dimension10, cf. \number7
- Change the lua table typetex.dimen to accept and return float values instead of strings
- Do something about \withoutpt10 and/or a new register type \real5?
- Implement the TEX primitive \htdp5?
- Do boxes with dual baselines.
- A way to (re?)calculate the width of a \vbox5, taking only the natural width of the included items into account.
